are 26 ft. diam. by 24 ft. 2 in. deep, built with a wooden cone bottom sloping 45 degrees. Each tank has an overflow launder bolted to the inside of the tank. The thickened slime as drawn continuously from an outlet at the bottom of the cone, contains from two to three parts of water to one of slime, and flows directly to a sludge storage tank or accumulator, 20 ft. diam. by 16 deep, with a 45-degree wooden cone bottom. The clear water overflowing the clarifying tanks is conveyed to a sump-tank 20 ft. diam. by 16 deep, from which is pumped direct to the battery storage tank back of the mill by a 9 by 10-in. Aldrich triplex pump. Sufficient cyanide and lime are added to the sludge storage tank to make a solution of 0.025% cyanide with a slight protective alkalinity. The pulp is agitated constantly by air, and is drawn at regular intervals directly to the two filter-presses. The slime-presses are of the well known Merrill type,* containing 64 four-inch frames, filled from a 6-in. pipe under 30 lb. gravity pressure, and discharged without opening by means of the rotating sluicing pipe with water under 60-lb. pressure. Owing to the talcose nature of the Silver Peak slime, the usual method of direct treatment in the presses has been somewhat modified. Instead of filling the frames until a solid 4-in. cake has been formed, the slime-feed is shut off while there is still an opening of about $\frac{1}{4}$ in. at the centre of the frame. As the feed valve is closed, the solution or water valve is opened, and the leaching of the cakes begins from the centre outward, the water or solution being introduced to each frame through a sluicing nozzle or rotating pipe. While it is perfectly practicable to leach in the presses with a secondary solution, it is found that the gold in the slime, which occurs in a fine state of division, is fully dissolved in the sludge storage tank. The main purpose of the presses, therefore, is to separate the dissolved gold from the slime. The displacement of solution by wash water is satisfactory and complete, there being little tendency for slime to classify if the pulp is maintained at a reasonably high gravity. Approximately eight parts of water to one of solid are used in sluicing the presses, most of this water being recovered by settling in a cone-bottom tank 24 ft. deep by 20 ft. diam. The final slime residue going to waste averages about $2\frac{1}{2}$ parts of water to 1 of solid, and could be discharged easily at 1 to 1 if desirable by providing greater settling capacity.

Zinc-dust is used for precipitation, the Merrill patented triangular press and process being used. Two distinct solutions are handled, the weak solution from the sand tanks and the combined low solutions from the sand and slime. A 12-in. rubber belt-conveyor, mounted on suitable rollers, is arranged to operate by means of floats and counter-weights at a rate proportional to the volume of solution pumped from the tank. The dry zinc-dust, being spread uniformly along the belt, is discharged into a mixing cone at a rate proportional to the tonnage of solution to be precipitated. A jet of air agitates the

emulsion, and a small stream of barren solution provides a constant overflow, which carries the zinc-emulsion down a $1\frac{1}{4}$ -in. pipe to the suction of the pump. No zinc is allowed to escape directly into the tank, and the precipitation takes place entirely during the passage of the solution through the pump, the pump-column, and the press. The latter contains thirty 2-in. triangular frames, 52 in. across the top, and has a total filter area of 450 sq. ft. The solution enters each frame from the top side channel and passes through a core to the bottom of the frame. Any zinc left in the frame from a previous pumping is kept in thorough agitation by the incoming stream of solution, and any excess of zinc deposited in the press during one pumping will be available for further precipitation during some future pumping. The efficiency of this method lies in the fact that the cloths are coated with a layer of powdered zinc and precipitate, so that every particle of solution having to pass through the cloth necessarily comes into intimate contact with the fine zinc, and also in the fact that to each tank of solution fresh zinc is added, assuring good precipitation, even of a solution containing copper. This can seldom be done with zinc-shavings, owing to their tendency to become inert when coated with copper.

The weak solution, after precipitation, flows to the barren weak-solution storage. The low solution is precipitated in like manner, but the barren 'low' flows to the water tank and is pumped to the sluicing tank, when it becomes the main supply for sluicing the slime-presses and sand tanks. One press serves for all solutions precipitated in the plant. It is necessary to clean the press twice a month. The cleaning and re-dressing with new cloths requires about four hours for two men. The filters used are changed at each cleaning of the press, but are washed and re-used several times. The following figures on precipitation are averages for March 1909:

	KCy. %	—Precipitation—	
		Gold. Head.	Gold. Tailing.
Weak solution	0.095	\$8.19	\$0.016
Low solution	0.025	0.85	0.020

The refining process used at this plant is practically identical with that in use at the Homestake.* Briefly, it is as follows: The precipitate is taken directly from the triangular precipitating press and placed in a lead-lined steel tank, where it is made into a thick sludge by adding water and agitating with mechanical stirrers. The free zinc is dissolved by hydrochloric and sulphuric, or by sulphuric acid alone. After acid treatment the sludge is deposited in a small filter-press. The zinc sulphate and other salts soluble in the acid solution or in water are carried away to a waste tank. Several washes of hot water are used after the precipitate is in the press, to make sure that all soluble salts are removed. The press is then opened and the acid-treated product is placed on a steam dryer, where it is dried sufficiently to be screened and sampled. After this a flux, consisting

*'The Metallurgy of the Homestake Ore', by C. W. Merrill, *Trans. A. I. M. E.*, October 1903.

of litharge, borax, and ground coke, is added and mixed thoroughly with the precipitate. This mixture is then briquetted at a pressure of about 1000 lb. per square inch, the object being to avoid 'dusting'. The briquettes are melted in a cupel furnace. During the fusion the gold is thrown down in lead, while the slag is run off into pots and later re-run in a small blast-furnace, together with cupel bottoms, sweepings, and other by-products. The cupellation of the lead is carried on in the same furnace, and the lead is separated from the precious metals by blowing a light air-current across the surface of the molten metal, thereby oxidizing the lead, which is drawn off from the front of the cupel as rapidly as it is formed. The litharge takes out very little value, and is re-ground and used the following month as flux. The bullion from the cupel furnace is then cut up and re-melted in graphite pots and cast into bars for shipment. The amalgam from the stamp-mill, after retorting, is melted and cast into bars in the same manner.

All men employed in mill and cyanide plant work 8 hours. The regular mill-crew consists of 3 men on a shift. In addition to this number are 2 plate-men and 2 repair-men on the day shift, making in all 13 men for the 24-hr. day. In the cyanide department 4 men are employed on each shift, with no extras on the day shift, making the total cyanide crew 12 men for the three shifts. In the refinery 2 men are employed, on day shift only. Their work consists of cleaning the precipitation-press and carrying on all work connected with the refining of mill and cyanide products. In the assay office, where the assaying for the mine and plant, as well as some custom work, is done, 3 men are employed.

Below will be found tabulated costs per ton of ore milled for six months, including office, administration, and insurance expense, but not interest and depreciation of plant:

COST PER TON.					
Month.	Milling.	Cyaniding.	Assaying.	Refining.	Total.
October	\$0.932	\$0.772	\$0.068	\$0.070	\$1.842
November . . .	0.913	0.681	0.072	0.113	1.779
December . . .	0.773	0.677	0.079	0.095	1.624
January, '09.	0.760	0.630	0.062	0.159*	1.609
February . . .	0.595	0.583	0.067	0.106	1.351
March	0.564	0.496	0.053	0.058	1.171

*Refining costs high this month, due to making a general clean-up of the solution sump-tanks, in which a gelatinous precipitate had been deposited while using brackish water from a salt marsh, which contained sulphates and carbonates.

These milling costs, as far as known, are less than one half those of other plants operating under conditions found in Nevada. The following figures relative to the cost of labor, power, and water for the entire milling plant (mill and cyanide) furnish an interesting comparison with similar data published of other Nevada companies:

Month.	Labor.	Power.	Water.	Total.
October	\$0.594	\$0.236	\$0.194	\$1.024
November . . .	0.488	0.237	0.110	0.835
December	0.451	0.237	0.100	0.788
January, '09	0.433	0.213	0.103	0.749
February	0.374	0.139	0.080	0.593
March	0.389	0.198	0.081	0.668

The cost of chemicals per ton of ore treated for the same months were as follows:

Month.	Cyanide.	Zinc.	Lime.	Acid.	Total.
October	\$0.221	\$0.058	\$0.047	\$0.033	\$0.359
November . . .	0.190	0.046	0.047	0.030	0.313
December . . .	0.194	0.044	0.044	0.021	0.303
January, '09.	0.176	0.060	0.037	0.060	0.333
February . . .	0.160	0.036	0.032	0.025	0.253
March	0.106	0.017	0.036	0.013	0.172

For the last quarter of 1908 and the first quarter of 1909, 64,052 tons of ore were milled. The net Mint returns on the bullion shipped show a total recovery of 92.3% of the gross value of the ore. Of these recoveries, 66% were made on the plates and the remaining 34% by cyaniding of sand and slime. The method of treating the sand in the secondary plant is practically the same as that used at the Homestake, modified to suit the local conditions. In the selection of a process suitable to the ore, crushing in cyanide solution was carefully considered and rejected because of the importance amalgamation plays in the recovery, and the difficulty of maintaining amalgamation at a high efficiency when solution is passed over the plates. While some of the ore contains considerable lead and iron sulphide, and the presence of these, especially where the lead and iron sulphides occur jointly, are excellent indications of good assay-value; the concentration of the sulphides, however, does not materially concentrate the precious metals. Concentration is, therefore, impracticable. By fine grinding, a small additional recovery, dependent on the grade of the ore, could be obtained. This, however, would necessitate the installation of a re-grinding plant, and also more slime-presses, and it is not considered that the additional recovery would justify such an installation on a comparatively low-grade ore. George O. Bradley was employed by the company during the construction and erection of this work.

Coal occurs at many localities in the Rogue River valley of southwestern Oregon, between the Cascade mountains on the east and the Klamath mountains, locally called the Siskiyou mountains, on the west. A long narrow coal belt stretching to the south and southeast in the Rogue River valley east of Medford and Ashland, Oregon, and continuing through the Siskiyou Mountain divide into California, a total distance of nearly 100 miles, has been described by J. S. Diller of the U. S. Geological Survey.

Old steam-engine plants can practically be doubled in power by the addition of low-pressure turbines and about 40% more boiler-capacity. With this increase, the steam engine must be capable of developing its full power on atmospheric exhaust, and this demands some re-adjustment of the valve gears for smooth running. Naturally, the conditions of running and the proportions of the cylinders should be known before designing the turbines, so that the two may operate well together.

Carbon monoxide in chimney gases increases with the imperfect combustion of the fuel; hence it is generally connected with the emission of smoke.

ORIGIN OF THE GOLD OF THE RAND.

By JOHN W. GREGORY.

*The wealth of the Rand goldfield depends upon its sheets of gold-bearing conglomerate or pebble-reef, known as 'banket'.

The sedimentary origin of this pebble-reef is unquestionable. Opinions have differed as to whether the conglomerates were of fresh-water or of marine origin; but it is now generally agreed that they were laid down upon a sea-shore. This pebble-reef being sedimentary, it was natural at first to regard the gold as also of sedimentary origin, like the Cambrian placer-deposits of Dakota.

Facts, however, were soon forthcoming that led to the establishment of various other explanations, of which the most serious rival to the placer theory has been that which regards the banket as conglomerate that has been mineralized by the entrance of gold-bearing solutions; it is held that the solutions mineralized the pebble-beds and not the adjacent quartzites, as the pebble-beds were more open to the entrance of solutions than the fine-grained sandstones.

The gold-bearing conglomerates are members of the thick series of sedimentary rocks, including shale, quartzite, and conglomerate, which constitute the Witwatersrand system. They have been invaded by many basic igneous rocks and are disturbed by a complex system of faults.

The Witwatersrand system was at one time regarded as Devonian in age, but it is certainly older than that date. It may be Paleozoic, but the probability is in favor of its being pre-Cambrian. It is not in contact with any fossiliferous rocks earlier than those of Karroo, so there is no precise evidence of its age; but it is probably Algonkian. The Witwatersrand formation has been folded into a syncline about 100 miles long from east to west and about 50 miles broad from north to south. The Witwatersrand system is covered by a wide series of amygdaloids, which are themselves covered unconformably by a series of rocks beginning with the Black Reef series. This series is in turn covered by the dolomites of the Pretoria beds, and above another unconformity lies the Waterberg sandstones, which are regarded by some authors as Devonian but by others as pre-Cambrian.

The Witwatersrand System rests upon the weathered surface of an older granite, which was intrusive into some schists. These schists are therefore older than the banket and its interstratified quartzites. The schists are not now exposed near Johannesburg, but they probably once covered the granite in the hills to the north of the Rand. The intrusion of the granite probably led to the formation of numerous quartz-veins in the schists. The quartz pebbles of the conglomerates are doubtless fragments of such veins.

According to the placer theory, the quartz veins were auriferous and supplied the gold as well as the pebbles. The beds of pebble-reef or banket are found on various horizons: a bed may consist of one layer

of conglomerate or of several seams separated by layers of quartzite and silicified shales. The separate beds of pebble-reef are thin, although they may have a great horizontal range. The conglomerate seams constantly vary in thickness; they disappear on one horizon, while another seam of conglomerate appears at a somewhat different level. The conglomerates in fact are subject to the usual variations of layers of shingle interbedded with sand along a coast. The most important beds of banket can be followed for great distances along the Rand.

All the conglomerate is not payable. The thicker seams, such as that known as the Main Reef, are often so poor in gold as to be unworkable. The richest ore comes from thin seams of conglomerate, such as the Main Reef Leader or the South Reef Leader. Even in the rich seams there are wide patches which are too poor to pay for mining with present costs; and these patches may be recognized on the stoping plans as large unworked areas that are usually lenticular in shape.

The arguments in favor of the impregnation theory have been summarized by Hatch and Corstorphine.¹

The first fact on which they rely is that the gold is found in the matrix of the conglomerate and not in the quartz pebbles; but this feature is one of those in which the banket agrees with alluvial gold deposits. The quartz pebbles in a placer gravel are fragments of the more compact and denser parts of quartz lodes, and as a rule such quartz is barren. Gold is usually deposited in quartz lodes along cracks which allow the circulation of the auriferous solutions; and even if the cracks be completely filled, the sheets in the lode containing gold and metallic sulphides would be inevitably weaker than the intervening masses of compact 'buck-quartz'; hence when vein-quartz is being broken up into gravel, it breaks most readily along the auriferous layers. The first process in the treatment of ore at an ordinary placer mine is the separation of the barren quartz pebbles from the gold-bearing cement. The presence in the banket of the Rand of occasional pebbles containing gold as a primary constituent is, however, asserted on good authority. Such pebbles may occur, and if they are as scarce as in a modern placer, their rarity would justify the view that the gold is practically confined to the matrix.

The second argument against the placer theory is that the gold is not angular or water-worn, and occurs in crystalline angular grains associated with secondary crystals and concretions of pyrites. This well established fact, however, merely shows that the banket is not a modern unaltered placer. The Rand pebble reef occurs in one of the oldest of sedimentary rocks, and it has been subject to such intense pressure that abundant crystals of chloritoid have been developed in the quartzite, shale, and cement of the banket series. In the compression of the conglomerate the fine flakes of soft gold were inevitably squeezed into the crevices between the hard sand grains and thus received their jagged angular outlines.

¹Abstracted from a paper read and discussed before the Institution of Mining and Metallurgy, London, and summarized by the author in *Economic Geology* of March 1909.

¹"Geology of South Africa." 1905. Page 146.

The gold is often associated with rounded concretions of pyrite, and the theory that the Rand is an old placer deposit has been prejudiced by the argument that all these rounded pieces of pyrite are rolled pebbles. It has been held that as the rounded pellets of pyrite are of alluvial origin, so also was the gold associated with them. But the occurrence of rounded pebbles of pyrite on an ocean beach is most improbable from chemical considerations. The advocates of the infiltration theory insist, and no doubt justly, that these rounded pieces of pyrite cannot have been originally pyritic pebbles. Some of them may be concretions; but the typical pebble-like pyrite and many seams of pyrite, which in their arrangement closely resemble the layers of black iron sand on a sea beach, are, in my opinion, pseudomorphic after iron oxide. Some of the pebble-like fragments of pyrites were certainly beach-worn pebbles; but they were pebbles of hematite, which has been converted into pyrite.

The crystalline nature of some of the gold is also natural in so ancient a deposit; since it has probably been dissolved and redeposited during the formation of the pyrite, much of which is admittedly of secondary origin. According to my opinion, much of this pyrite is altered black iron sand; the iron oxide has been converted into sulphide, and the ferric sulphate solutions formed during this reaction probably dissolved the fine gold and re-precipitated it almost in place.

In the discussion before the Institution of Mining and Metallurgy stress was laid by some advocates of the infiltration theory on the improbability of the solution and precipitation in place of gold. In the paper then discussed the Kanowna lead in Western Australia was quoted as an example of the localities where this process must have occurred. The Cambrian placer deposit near Deadwood, South Dakota, provides another and better known illustration.² The evidence in that case was clearly stated by W. B. Devereux, and it has been advanced with still greater authority by J. D. Irving.³ "The gold," says Professor Irving, "is known to occur in two conditions: detrital gold and chemically precipitated gold; in addition, much of it may have been introduced with pyrite." He concludes, "Unfortunately, it does not seem possible to determine what proportion of gold in the pyritic conglomerate is detrital or was there before the pyrite was introduced. There is also a possibility that some of the gold in the lower and unoxidized portions may be precipitated gold resulting from secondary concentration."

The solution and precipitation of the gold in these Cambrian placers has indeed led to the view that they owe all their gold to infiltration. But in this case the gold is coarse and the rocks unaltered; so that the rounded detrital form of the gold has been retained.

The third argument advanced in support of the

infiltration theory of the formation of the Rand is the uniform distribution of the gold. This uniformity has, however, been exaggerated in the literature. It has been stated that the blanket is as persistent and uniform in its yield as a coal seam. But such is not the case. The detailed assay-plans of the mines show that the blanket is subject to sudden and extreme variations in value.

The variations affect both adjacent samples and the average yield of large areas of the pebble-reef. Frederick Hellmann, of the East Rand Proprietary, has prepared diagrams showing the variations in value along a continuous band of reef; and he has aptly called them his "icicle diagrams," as the line representing the gold values rises and falls as sharply as the outline of a row of icicles. The irregular distribution of the gold in the pebble-reefs could be illustrated from the assay-plans of most of the mines. Similarly adjacent areas show great variations of value. One has only to consider the fact that in the year 1904, out of the 64 producing mines on the Rand only 33 paid dividends to realize that the gold yield of the reef is not uniform; and study of maps showing the distribution of the producing mines along the Rand, or a traverse in the field of the large unworked gaps in the line of mines between Krugersdorp and the East Rand affords impressive proof of the irregularity of the gold distribution. The gold-bearing blanket has admittedly a greater length of rich ore than any other marine placer; but it does contain wide barren sections, and the rich deposits contain barren patches, like ordinary placers.

The fourth objection to the placer theory is the restriction of the gold to certain definite beds. This arrangement is, however, not inconsistent with the alluvial origin of the pebble-reef, for it is actually the rule in placer deposits. The nature of the restriction of the gold distribution in fact affords one of the strongest proofs of the detrital origin of the gold.

A further argument against the placer theory is worthy of notice, as much stress was once laid upon it, though the argument has been generally abandoned. It was the absence of nuggets or of coarse-grained gold. This fact admits of two simple explanations. When alluvial gold is derived from reefs, in which the gold is present only in fine particles, then the gold in the placers formed by the denudation of these reefs is also fine. In the case of the Rand, even if there had been coarse gold in the reefs it would probably not have reached the shore deposits; for rivers were probably the main agent in the destruction of the gold-bearing reefs; and any heavy gold that they may have obtained from the reefs would have been deposited on the river bed, or ground into fine particles before it reached the sea. As with the placers on the western coast of New Zealand, only the fine gold would have been carried onto the beaches, and then distributed by the currents along the shore.

The objections to the placer theory seem to me therefore all invalid; while those to the impregnation theory appear insuperable. No trace has yet been discovered of the 'verticals' or channels up which the solutions were introduced. In mining districts.

²W. B. Devereux, 'The Occurrence of Gold in the Potsdam Formation, Black Hills, Dakota', *Trans. Amer. Inst. Min. Eng.*, Vol. X, 1882, p. 471.

³J. D. Irving, 'Economic Resources of the Northern Black Hills', *Prof. Paper U. S. Geol. Surv.*, No. 26, 1904, pp. 109-111.

where sedimentary rocks have been mineralized by infiltration, as, for example, in the Cambrian gold ores of South Dakota, the channels by which the gold was carried into the sedimentary layers have been easily discovered. They are so clear that they have been illustrated by convincing photographs. No such channels have been discovered on the Rand.

The conditions under which the gold was introduced into the pebble-reef on the placer theory are shown by the nature of the reef and its pebbles. Before visiting the Rand I was unable to decide between the placer and infiltration theories, because, among other reasons, of the richness of the 'banket' in such fine gold. The most striking difference between the banket and any modern placer is that the gold is exceptionally fine-grained in proportion to its richness. I was, before visiting the Rand, prejudiced against the placer theory, as I failed to understand how such fine gold could have been concentrated into such rich seams. Equally fine gold is known in river placers; but it is there distributed through thick beds of fine silt, which would never have paid to work under such geological conditions as those of the Rand. Inspection of the richest seams of banket at once removed the difficulty, which was due to my not having allowed for the difference between marine and river placers. The richest seams on the Rand have large, well rounded pebbles, which show by their form that they have been subject to strong currents; the layers with angular pebbles—the bastard reef—are practically always so poor that they are unpayable, though assays show that some gold is generally present in the material. The richest deposits, like the Main Reef Leader, are thin layers of conglomerate, containing large, well rounded pebbles; the pebbles are sometimes thicker than the bed in which they lie, so that they project well above its upper surface into the quartzites.

Such layers were formed as sheets of shingle upon a sea-shore swept by strong tidal currents. The bun-shaped form of the pebbles, with their flattened base (the significance of which was explained by Becker) shows that they were spun around as they were moved backward and forward by the scour of the tide and thus the base worn flat. The waves breaking over them would have swept the light silt and mud from between the pebbles and the interspaces thus formed would have served as riffles; in the shelter of which the heavy gold would have collected. Thus there would have been a slow concentration of fine gold in the layers of coarser shingle which had been for a long while exposed to the surf. The formation of the bastard reef, on the other hand, would not have been accompanied by such concentration, for the angularity of its pebbles shows that it was not washed and rounded as thoroughly as the true banket. Hence, though gold is present, it occurs in such small quantities that the material does not pay to mine.

The distribution of the gold throughout the Rand agrees in its essential characters with its distribution in placer deposits. The gold is usually richest on the foot-wall side of a seam. The rare cases of the occurrences of visible gold in the banket appear to be prac-

tically always on the foot-wall surface of the seams. And when a bed of pebble-reef consists of several seams of conglomerate separated by an intervening layer of quartzite, it is usually the lowest seam that is the richest. This rule is of course not universal, and on the 'marine placer' theory exceptions would be expected; for the tidal scour would be strongest now at one point on the beach and now at another. Gold concentration would take place most effectively at different localities as the beach deposits were being accumulated. This connection between the concentration of the gold on slightly different horizons and the physical nature of the conglomerates is well shown by the continuous reef sections which have been prepared for many of the Rand mines.

The agent that spread the gold through these thin beds of shingle was one that had a widespread horizontal range of action, and was limited for each sheet to a narrow vertical range. This distribution is consistent with the action of the surf on a shore; but it is wholly inconsistent with the behavior of a mineralizing solution percolating through a series of sands and pebble beds. Occasional layers of shale in the Rand series would no doubt have been impermeable to the solutions and would have escaped mineralization, although they contain some gold; but the rich beds of banket often rest on thick layers of pebble beds, the bastard reef, which would have been as freely open to infiltrating solutions as the banket. Becker has clearly shown the fallacy of the assumption that the coarse sandstones associated with the pebble beds would have been comparatively impermeable. And the bastard reef must often have been more open to solutions than the adjacent banket, when the latter consists of large pebbles in a compact matrix.

It is so obvious that any gold-bearing solutions that circulated along the layers of banket must have percolated into the underlying bastard reef that the suggestion has been made that the distribution of the gold was determined by some precipitant present only in the banket. The precipitant suggested is organic matter, as traces of carbon have been found; but the organic matter would have existed equally, and probably even more abundantly in the quickly accumulating bastard reef, as it was subject to less violent scour than the banket. So far there has been no adequate evidence of any precipitant that would explain the deposition of the gold in the surf-washed Main Reef Leader, and would be absent from the underlying bastard reef.

Probably the weightiest evidence between the two theories is that afforded by the microscopic structure of the ores, as that evidence can be most easily aduced. The microscope when applied to thin sections of an ore reveals the actual history of its formation. If the banket had been impregnated by solution the microscope should discover the channels along which the gold has come. The microscope shows that the deposits have been silicified; that chloritoid is abundant and has probably, as usual, been developed by pressure; and that the iron pyrite is secondary; but it reveals no evidence of mineralization by solution as in an ordinary gold-quartz vein. Where gold ores

have been formed by solution acting upon older rocks, the solutions have altered the rocks into sheets of vein-quartz, which in the less altered specimens show remains of the original minerals. But microscopic sections of rich specimens of banket show that they have been no more altered than quite poor specimens.

The petrographic evidence shows that the minerals characteristic of the banket, such as the chloritoid (ottrelite) are characteristic of pressure and earth movements, and not of the action of mineralizing solutions. Pyrite is no doubt often present in gold-quartz veins; but it is still more widely distributed in clays, in which it has been formed by the action of sulphuretted hydrogen derived from decomposing organic matter on iron oxides.

Until the advocates of the impregnation theory discover the channels up which the gold has been introduced, produce evidence of adequate chemical change in the rich banket, explain the limitation of the gold to certain horizons and its absence from equally permeable or even more permeable adjacent layers, the impregnation theory must remain as a hypothesis with very little evidence in its support. On the placer theory there is no difficulty in understanding the introduction of the gold into the banket and its present distribution.

Native sulphur near Thermopolis, Wyoming, according to E. G. Woodruff of the U. S. Geological Survey, occurs in two forms—in small yellow crystals filling veins or cavities in the rocks, and massive where the original structure of the limestone is retained but where the calcium carbonate is replaced by sulphur. The sulphur is found in crevices, channels, or cavities such as watercourses make where they traverse limestone beds. The cavities seem to be portions of subterranean channels through which hot sulphur-bearing waters flowed, and on the walls of which the sulphur was gradually deposited until the chambers were completely filled or, in some places, only partly filled before the passage was stopped at some point and the water diverted to other channels. No regular arrangement of the cavities can be discovered, although they seem to occur in groups at places where the water found free passage. In areas between the groups of cavities only a small amount of sulphur is present, but in the enriched pockets the amount reaches 30 to 50% of the rock or even more, and becomes commercially important. Some of these abandoned watercourses are arranged in a close network, with the interspaces so completely mineralized that the whole area is now a mass of sulphur. Laterally a deposit may be rich at one point and barren 10 ft. away. The sulphur ore thus varies from a low percentage associated with barren rock to small masses of the almost pure mineral, but as the deposits follow no general laws, all of the area where geologic conditions are favorable must be tested to find them.

To authorize a private person to maintain an action to abate a public nuisance he must show a special injury, different in kind and not merely in degree, from that suffered by the public generally.

YERINGTON COPPER DISTRICT, NEVADA.

The copper mines and prospects in the vicinity of Yerington, Nevada, were examined during the season of 1908 by F. L. Ransome of the U. S. Geological Survey, and a report of the work has just been published (Bull. 380). The town of Yerington is in Lyon county, in that part of western Nevada which lies between Tahoe and Walker lakes, and the nearest railway station is Wabuska, 12 miles to the north. The town is in the middle of Mason valley, through which Walker river flows northward for some 25 miles before turning to the east, near Wabuska, around the north end of the Walker range, on its course to Walker lake. The principal copper mines are west of the town, in the mountain ridge of which the Indian name is said to be Singatse. It is also called the Smith Valley range. The ridge has an average width of 4 miles, and the crest is from 1600 to 2600 ft. above the valley at Yerington, or from 6000 to 7000 ft. above the sea. The mines constitute a chain about two miles long, lying on the east slope of Singatse ridge, about half way between valley and crest, 4 to 8 miles from Yerington. At present operations are confined to developments in the zone of sulphide ore or, at one mine, in a zone of mixed sulphide and oxidized ore. Another group of copper prospects lies in the low hills 4 or 5 miles southeast of Yerington. The total quantity of oxidized ore exposed in the district is small, and there is no indication of any extensive sulphide enrichment. The quantity of gold or silver in the ores is practically negligible. The future of the mines depends on the working of low-grade primary deposits. The conditions are in some respects favorable for cheap mining and concentrating; a railroad could be constructed from Wabuska along Walker river with little difficulty. Water is more plentiful than in some other parts of Nevada, and many agricultural products can be grown in Mason valley.

The Tres Hermanas mountains rise from the general level of the high plateau about 25 miles south of Deming, N. M., and 10 miles north of the Mexican boundary line. The highest of the peaks attains an elevation of more than 7000 ft. above sea-level. Lead was discovered in this group at an early date, and for many years mines in the northern part of it have yielded a moderate production, possibly to a total value of \$200,000. In 1904 attention was attracted to a heavy white massive or crystallized material occurring plentifully in old lead workings, and this material was found to consist of carbonates and silicates of zinc. The zinc ores include large quantities of the unusual mineral willemite (the pure anhydrous silicate of zinc), smithsonite (zinc carbonate), hydrozincite (basic zinc carbonate), and calamine (hydrous zinc silicate). Shipments of the zinc ore were made to smelters in the Mississippi Valley in 1905, but in 1906 and 1907 little activity was apparent. A geologic examination of the north end of the Tres Hermanas district was made during the field season of 1908 by Waldemar Lindgren of the U. S. Geological Survey.

DISCHARGE FORMULAS FOR CAST-IRON PIPE.

By GEORGE L. BEAN.

*I have made a comparison between a simple formula recently presented by C. C. Vermeule, a rough formula of my own, and the various standard formulas for discharge of water from cast-iron pipe, with the following result:

Twelve formulas were calculated for slopes of 2 to 5 ft. per 1000, and for diameters of 4 to 30 in. Of these only three give concordant results, namely, those lettered (c), (h), and (o). Taking the formula

TABULAR COMPARISON OF VARIOUS PIPE-DISCHARGE FORMULAS. FOR CLEAN CAST-IRON PIPE; DISCHARGE IN UNITS OF 1,000,000 GALLONS PER 24 HOURS.											
Formulas Tabulated:						Source:					
(a)	$Q = 0.05 d^2 \sqrt{d s}$					Vermeule, Engineering News, January 21, 1909.					
(b)	$Q = 0.001760 d^2 \sqrt{h d}$										
(c)	$Q = 0.00354 d^2 \sqrt{\frac{h}{F}}$					Weston's tables, $v = \sqrt{\frac{h}{F}}$					
(d)	$Q = 0.00354 d^2 \sqrt{\frac{2 g r i}{m}}$					Fanning, $v = \sqrt{\frac{2 g r i}{m}}$					
(e)	$Q = 39.528 D^{2.694} s^{0.555}$					Lampe, $q = 61 D^{2.694} \left(\frac{H}{L}\right)^{0.555}$					
(f)	$Q = .30578 d^2 D^{\frac{5}{8}} S^{\frac{1}{2}}$					Flamant $v = 86.38 D^{\frac{5}{8}} S^{\frac{1}{2}}$					
(g)	$Q_{010} = 1.68 Q_{015}$					From Kutter's formula (and Swan & Horton)					
(h)	$Q = 0.00354 d^2 c \sqrt{R S}$					Darcy, $v = c \sqrt{R S}$					
(k)	$Q = 0.00354 d^2 (97.05 \sqrt{R S} - .08)$					Prony, $v = 97.05 \sqrt{R S} - .08$					
(k ₁)	$Q = 0.00354 d^2 (99.88 \sqrt{R S} - .154)$					" $v = 99.88 \sqrt{R S} - .154$					
(m)	$Q = 0.00354 d^2 (108 \sqrt{R S} - .13)$					Eytelwein, $v = 108 \sqrt{R S} - .13$					
(m ₁)	$Q = 0.177 d^2 \sqrt{\frac{D H}{L + 50 D}}$					" $v = 50 \sqrt{\frac{D H}{L + 50 D}}$					
(n)	$Q = 0.16992 d^2 \sqrt{\frac{D H}{L + 54 D}}$					Hawksley, $v = 48 \sqrt{\frac{D H}{L + 54 D}}$					
(o)	$Q = 0.00354 d^2 (140 \sqrt{R S} - 11 \sqrt[3]{R S})$					Neville, $v = 140 \sqrt{R S} - 11 \sqrt[3]{R S}$					
The symbols have the following meaning:						L = length, total.					
v = velocity, feet per second.						S = sine of slope.					
Q = discharge, units of 1,000,000 gals. per 24 hrs.						R = hydraulic radius, ft.					
q = discharge, cubic feet per second.						F = Weston's factors.					
d = diameter of pipe, inches.						c = Darcy's constants.					
D = diameter of pipe, feet.						having values as follows:					
s = fall in unit length.											
h = fall in ft. per 1,000 ft.											
H = fall, total.											
Fall, 2 ft. per 1,000.

*Abstracted from Engineering News.

(c) as a standard, the other two compare extremely well with it. An approximate agreement with these is found also in the two simple or rough formulas (a) and (b). The former is, for 4 in. diam., 3% too low (which is close enough), and for 30 in., 12% too low (not close enough), the variation increasing with the size of the pipe. Formula (b) is recommended for pipes from 6 in. diam. up, the discharge being about 4% in excess for 6 in. to about 2% too low for 60 in. with a slope of 5 in 1000 (an extreme slope, giving about three times the economical velocity for 60-in. pipe). Formulas (c), (h), (o), and (b) apply to long, clean, cast-iron pipes as ordinarily used for water-supply and distribution systems.

SPECIFIC GRAVITY OF CONCENTRATE.

Written for the MINING AND SCIENTIFIC PRESS
By EDGAR B. VAN OSDEL.

Several years ago, while chemist for the Frisco mine, in the Coeur d'Alene, I had occasion to make frequent specific gravity determinations on various sizes of concentrate. These determinations were useful chiefly on account of the large amount of magnetite associated with the galena, and also in checking the quality of the zinc concentrate and tailing.

The first two compartments of the jigs would make a good grade of lead, but the third invariably produced a mixture of clean sphalerite with particles of the same specific gravity, but consisting of galena and magnetite. This was afterward run through a magnetic separator, which removed the latter product from the zinc. Likewise, on the tables, between the bands of lead and zinc, appeared a black band of this galena-magnetite mixture. Hence the necessity for specific gravity determinations to check the work of these machines. For the large sizes, at first, the regular method of weighing a particle suspended first in air, then in water, was used. Then the usual calculation of $\frac{W}{W-W'}$ gave the desired result. But the finer concentrate could not be treated in this manner, and since $W - W'$ represents the displacement of water in grams, the following scheme was used: A burette is filled to some convenient point, approximately 30 c.c., with water of the proper purity and temperature, and a reading taken. Then as large an amount of concentrate as can be conveniently handled, say 20 gm., is weighed accurately and transferred by means of a sheet of glazed paper to the burette. Of course much of it adheres to the sides of the burette and must be washed down by inverting it when closed by the thumb. When the dry concentrate is all moistened and settled below the water the second reading may be taken and the weight of the displaced water in grams calculated. The weight of the sample divided by this gives the specific gravity.

This method proved so satisfactory and so accurate on account of the large sample that it was also applied to the larger sizes by crushing them small enough to enter the burette before weighing. In this case, however, care must be exercised to prevent loss from dusting, since material lost in this way proved to be the softer and heavier galena.

CONTINGENT FEES.

By H. M. CHANCE.

*It will perhaps be admitted that an advocate, a partisan, or a promoter may properly accept compensation which in amount is contingent upon the success or failure that attends his efforts. Doubtless it will likewise be thought proper for a manager, inventor, or constructor to agree that the amount of his compensation shall depend upon the result achieved. Whether it be proper or expedient for an advisor or counsellor to agree that his services shall be paid for by their value, as measured by economic or financial results, is not so clear.

We have not the temerity to ask whether an appraiser, an arbitrator, or a judge may properly be compensated in proportion to the value of his findings to any of the parties in interest, for such a query appears absurd and its proponent ridiculous. To discuss this matter of contingent fees or contingent compensation intelligently, it therefore seems necessary first to define the position of the 'engineer', to learn in what capacity he is acting, whether as advocate, promoter, manager, advisor, or judge, and whether his position is a business or commercial one, or is purely professional.

As the engineering profession embraces those engaged in many widely different fields of activity; as many who are normally or usually employed in a certain class of work often enter some other sphere, where their duties, relations to principals and to the public are radically changed, recognition of these conditions becomes imperative before questions of ethics or of business or professional expediency can profitably be discussed. Those engaged in managerial work cannot adopt rules of conduct which might be formulated for those engaged in purely advisory work; nor can the tenets held by the salaried employee be applied to one who may be owner, vendor, or promoter. It seems to me that the Society should endeavor to define, in some way capable of easy application, the difference between the advisory functions of the engineer when reporting upon or appraising the value of properties, and those other functions which he may perform as manager, as part owner, as promoter, or as a business representative. The confusion of the public as to the proper place of the engineer arises from the many different spheres of activity to which engineers turn their attention, or into which they are drawn, in their efforts to make a livelihood.

When an architect becomes the superintendent of construction for a firm of contractors, for the time being he ceases to be recognized as a professional architect; when a civil engineer becomes division superintendent of a railroad, he is no longer a civil engineer; and even when a lawyer becomes president of a corporation, the public no longer regards him as a professional man; yet many mining engineers continue to be known as mining engineers for many years after they may have ceased entirely to do any professional work. This breeds confusion in the public

*Abstracted from discussion before the Mining and Metallurgical Society of America.

mind, and a vague idea that the mining engineer is properly manager, inventor, promoter, or advisor at the same time, and consequently may be expected to act as his interests and those of his principals may require. For reasons that are well known, those engaged in consulting practice and those engaged in teaching more generally receive public recognition as professional workers than those employed in managerial or commercial work, but as the latter are constantly changing positions with the former, it seems impossible to prevent misconception as to what constitute proper rules of conduct.

When acting as advisor, appraiser, arbitrator, or judge of property, the engineer might consider a contingent fee or contingent compensation as impossible of contemplation; if acting as a vendor, promoter, part owner, in matters connected with the sale or financing of property, the engineer might consider it proper to accept compensation contingent upon the financial outcome of the project; if acting as manager, inventor, constructor, or designer the engineer will likewise claim the right to be paid in proportion to the degree of success or failure that attends his efforts. It would appear then that the only part of the question that is debatable is whether an engineer acting as advisor, appraiser, arbitrator, or judge of the value of property can in any circumstances be justified in accepting a contingent fee.

COOLING TOWERS.

By SAMUEL K. PATTESON.

*Of all the recent developments in the construction and operation of power-plants, the cooling tower has advanced with probably greatest rapidity. As an engineering development it has passed the experimental stage. While the prime object is the same, cooling towers have been installed for two entirely different reasons; first, the difficulty of obtaining large supplies of water, or its procurement at large cost, and, second, the necessity for using water undesirable on account of impurities.

The cooling tower is based simply upon the absorbing power of the air for water-vapor and the consequent cooling of the water from which this vapor is obtained.

Generally speaking, there have been two kinds of cooling towers developed, as a result of experiment and use, and these are called, respectively, the closed and the open or atmospheric type. These two types are in many respects the same, in that both consist of a square, rectangular, or round tower rising into the air from 20 to 60 ft., and having water-pipes for conveying the hot water to the top, with various sprinkling devices at that point to spray or distribute the water. The closed type differs, in theory at least, from the open type, only in the fact that the sides are closed and contact of the water with the air is accomplished by means of a power-fan placed at the base and forcing the air over the water. On the other hand, the atmospheric type has open sides to permit a free circulation of air.

The large surface necessary for exposure to the air

is obtained in many ways; for instance, the Burhorn and Hart types utilize a series of large shallow pans, one above the other, and slightly tilted, the alternate pans being parallel with each other, and the water either overflowing in these pans or escaping through a series of holes made in the bottom of each pan at the lower edge, falls by gravity over the bottom of each pan in succession. Slabs of wood or slate, similarly arranged and for the same purpose, are used in other designs. In another type the water is allowed to run into a series of horizontal parallel V-shaped pans, which overflow when full, and the overflow is caught by a similar series of pans placed below the first, and so on through the entire height of the tower; or the V-shaped pans may have apertures in the apex of the V, thereby allowing the water to escape to the lower levels. In the closed type, the Alberger tower has a series of horizontal parallel cypress planks, equidistant from each other and resting on their narrow surface, superimposed at right angles upon another similar series, and so on for a number of layers; while the Worthington tower consists of short vertical lengths of interlocking galvanized pipe arranged in layers, to permit of dividing the water into innumerable channels as it descends.

In comparing the relative efficiency of the two types, the closed type was formerly considered to be superior, due to the fact that the fan was supposed to force much more air over the surface of the water than in the atmospheric type. It is found that the air rapidly becomes saturated, and is ineffective during the latter part of its passage over the water. In this type, therefore, a given quantity of air, forced into the lower part of the tower, must, in ascending, come in contact with and move parallel to constantly falling streams of water, and after absorbing from the water which it first reaches, its full quota of water-vapor, it is practically useless during the remainder of its progress; whereas in the open type the descending water is brought into contact with an air-current moving nearly always at a right angle to it, and never parallel, so that the water passes through successive layers of air that will take the water-vapor from it. It is therefore recognized today, from an operative point of view, that the atmospheric type is superior in cooling efficiency. The fact that in the closed type the operation of the fan requires power, and that this latter must be considered as a cost factor in the operation of the plant, has also enabled the open tower to successfully compete with its rivals.

The quantity of salt produced in this country in 1908, according to statistics compiled by the United States Geological Survey, amounted to 28,822,062 bbl. of 280 lb., valued at \$7,553,632, a decrease of 882,066 bbl. in quantity and of \$54,691 in value from the output in 1907. Expressed on a tonnage basis, these quantities represent an output of 4,035,089 short tons in 1908, or 123,489 short tons less than the production in 1907. The average net value of the product in 1908 was 26.208c. per bbl., or \$1.87 per short ton, as against 25.614c. per bbl., or \$1.83 per ton, in 1907.

*Abstract from Cassiers Magazine

Evolution of an Idea.

Mining is as old as civilization, and prospecting still more ancient. The crooked stick served our forefathers for a plow about the time the miner began using the horn spoon in his search for gold. Science and invention have relegated the crooked stick to the museum of antiquities, but until recent years the miner had to rely on his primitive horn spoon. The hardy prospector has been seriously handicapped in his search for the precious metals for want of a simple portable device for testing any and all kinds of rock where found. The pan and horn spoon answer when the metals are free and coarse grained, but are a delusion and a cheat where the ore is base. To meet this demand, Henry E. Way has invented a 'pocket smelter'. The original aim of the inventor was simply to enable the miner and prospector to tell whether their rock contained any metal at all, and if worth while to assay or not; but the uses of the little smelters have grown from year to year and other devices have been added.

The original pocket smelter outfit consisted of mortars and pestles and smelter tablets; later a patent acid-dropping bottle and case were devised, which with a little 40-mesh wire screen substituted for the acid bottle and case, comprises what is now known as the 'little junior' outfit. All the manufacturers claim for this is a test for the presence or absence of metals. The demand for an outfit which would enable the various metals to be detected and identified, led the manufacturers to add a magnet, magnifying glass, patent acid-dropping bottle and case, and some minor articles, which constitutes what is known as the 'senior outfit'. With this a true qualitative analysis can be made on any ore of commercial value.

The addition of these articles made the outfit difficult to carry around in the pocket, which led the manufacturers to supply a leather-bound shipping and carrying case, in which every article fits so snugly that the omission of a single piece is at once noticed. A batea was provided for panning, and a rubber cloth for holding screened ore-pulp. The further demand for an outfit to extract and identify such rare minerals as tungsten, as well as for estimating ton values in ores by comparison, has led the manufacturers to place on the market the 'complete outfit'. This includes two extra boxes of smelter tablets, a batea in which to pan, with glass mortar, a number of assayed ore samples with ton values marked in dollars or per cent total, to serve as a 'comparison scale' in estimating values, together with an extra acid bottle and case, making two in all, by the combination of which aqua regia is formed, for use in the platinum and tungsten tests. This complete outfit is designed for the student, professor, mine owner, mine superintendent, and all desiring the maximum results at the minimum cost, and is for use in office, laboratory, and in the field. It is always ready for use in a moment.

The success of the 'pocket smelter' has been phenomenal, and it has steadily grown in favor with all classes. The limit of the utility and possibilities has not yet been reached. The original patent was for a device, but this has been elaborated and perfected until today it has become a combination of devices and parts, which will hereafter be designated as 'Way's process', to distinguish it from the blowpipe method, wet determinations, and assaying. The manufacturers make no false claims for Way's process, but guarantee results when instructions are strictly followed. It combines the good points of the blowpipe, wet methods, and the assay, in so far as they are practical on metals of commercial importance, without any of their imperfections. Quantitative determinations are left to those whose skill and technical knowledge of mineralogy and metallurgy peculiarly fit them for this work. Way's process, however, is being used for confirmatory tests, in connection with blowpipe, wet methods, and even assaying, and being so simple, inexpensive, and effective, the manufacturers confidently expect to eventually supplant all other methods except that of assaying. This useful outfit is made by Way's Pocket Smelter Co., of South Pasadena, California.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

PAVING BRICK AND PAVING BRICK CLAYS OF ILLINOIS. By C. W. Rolfe, R. C. Purdy, A. N. Talbot, and I. O. Baker. Illinois State Geological Survey, Bull. 9, 8vo., pp. 316, Ill., Index. Urbana, 1909. Postage 13 cents.

This report includes a discussion of the geology of clays in general, and of the paving brick materials of the State; of the qualities of high-grade paving brick, and of the tests used in determining them; of the qualities of clays suitable for making paving brick, and the pyrochemical and physical properties of paving brick clays; tests of the clays now in use and of the construction and care of brick pavement. The report is based on elaborate studies and is authoritative.

RESULTS OF PURCHASING COAL UNDER GOVERNMENT SPECIFICATIONS. By John Shober Burrows; and BURNING SMALL SIZES OF ANTHRACITE FOR HEAT AND POWER PURPOSES. By Dwight T. Randall. Bulletin No. 378, U. S. Geological Survey, 1909.

Commercial Paragraphs.

THE DENVER FIRE CLAY CO., Denver, announces that in the future it will carry a complete stock of assayers' and chemists' supplies in Salt Lake City, at 156 Southwest Temple street.

THE MILL & SMELTER ENGINEERING CO. has been formed to conduct a general business in designing and equipping mining and metallurgical plants. F. W. Hopkins is the manager and P. E. Van Saun is chief engineer. The office of the new concern is at 114 Liberty street, New York.

Catalogues Received.

THE TOLEDO PIPE THREADING MACHINE CO., Toledo, Ohio, has recently published an attractive catalogue describing its line of pipe-threading apparatus.

THE SCHUTTE & KOERTING CO., Philadelphia, is distributing a pamphlet called Section B of Catalogue 5, in which the multi-jet eductor condenser is described.

THE BROWNE & SHARP MFG. CO., Providence, R. I., has just published a new edition of its general catalogue. Special attention is called to the new machines, attachments, and small tools recently added to the line already carried by this well known house.

THE WESTERN ELECTRICAL INSTRUMENT CO., Newark, N. J., is distributing some novel private mailing cards giving lectures on 'Economics', 'Electricity', 'Mechanics', 'Logic', 'Physics', and 'Chemistry'. The company styles itself a 'Correspondence Institute' and gives its agents as 'Local Associate Instructors'.

MINING AND METALLURGICAL PATENTS.

ELECTRICAL SHOT-FIRING MACHINE FOR MINES.—No. 916,476. Walter B. McLarty, Wilburton, Oklahoma.

An electric shot firing apparatus for mines, comprising a generator, a rotatable controller arm, circuit closers mounted upon said arm, means for operating the latter, a conductor ring against which one of said closers is constantly in contact, electrical connections between said conductor ring and source of energy, a series of contact points against which the circuit closers upon said arm are adapted to contact at predetermined moments, electrical connections between said contact points, the source of energy and the charges to be fired, and an electric signal in the circuit with said ring, as set forth.

ORE-CONCENTRATOR.—No. 916,257. Samuel K. Behrend, Denver, Colorado.

In an ore concentrator the combination with a table, and means for reciprocating said table, of a hopper located at or near the middle of the table, a recessed roller in the bottom of said hopper, a shaft on which the roller is mounted, a ratchet wheel on the shaft, pawls engaging the ratchet wheel whereby the roller is intermittently rotated, a frame-work beneath the table in which the tailings are discharged through an opening at the upper end of the table, said frame-work having a constricted passage and two inclines leading from said passage, the space between the inclines being greater at the outer ends and one of the said inclines being longer than the other, and a suction fan beyond the constricted passage for creating suction of air.

APPARATUS FOR ROASTING AND SINTERING ORES.—No. 916,394. Arthur S. Dwight, Joliet, Illinois, and Richard L. Lloyd, New York.

In an apparatus for roasting and sintering ore, the combination of an endless ore support or carrier, having its successive ore-receiving sections rigidly secured together and all said sections being adapted to simultaneously move through a predetermined path, means for moving the said support, means for supplying air to permit it to pass through the ore mass in a direction transverse to the movement of the support, substantially as set forth.

PRODUCTION OF SILICON.—No. 916,793. George O. Seward, East Orange, New Jersey, and Franz von Kugelgen, Holcombs Rock, Virginia.

The process of producing silicon by subjecting a suitable silicon compound and a carbonaceous reducing agent in an electric furnace to a temperature above that at which silicon carbide remains stable, thereby reducing the silicon compound and forming silicon vapor, while maintaining around or above the zone of reduction a cooler zone containing a non-oxidizing atmosphere in which the silicon vapor is condensed.

PULP-SCREEN-PLATE FASTENER.—No. 918,261. Eugene A. Bayley, Dexter, New York.

The combination of a pulp screen frame having cross braces provided with longitudinal passages, dovetailed bushings within the passages and near one end thereof, threaded elements engaging the bushings to adjust the same, screens having beveled edges upon the cross braces, slidable beveled locking bars having dovetailed fingers upon the cross bars, said locking bars having their sides engaging the beveled edges of the screens and the dovetailed fingers adapted to be positioned within the passages of the cross bars, and a threaded element engaging one end of the locking bar to force the fingers thereof into engagement with the dovetailed bushings.

TRACTION-ROPE-GRIPPING DEVICE FOR AERIAL WIRE-ROPE TRAMWAY BUCKETS.—No. 915,104. James H. Montgomery, Denver, Colorado.

In a rope gripping device for the buckets of aerial wire rope tramways, the combination with a stationary and a running rope, of an operative tramway bucket, a fixed jaw connected to said bucket and arranged to register with the under side of said traction rope, a non-rotatable but slidable movable jaw mounted on said fixed jaw to register with the upper side of said traction rope, a cam arranged to move said movable jaw to grip said running rope between itself and said fixed jaw, resilient means for normally holding said movable jaw away from said running rope when said cam is in a position of disuse, and means including angular slideways for automatically moving said cam to attach said jaws to or to release them from said running rope.

FLUID-OPERATED DRILL-SHARPENER.—No. 917,777. John G. Leyner, Denver, Colorado.

In a drill sharpener, the combination with a supporting base, a cylinder provided with a drill supporting arm, a yoke-shaped standard on said cylinder, a die at the upper end of said standard, a fluid controlled piston reciprocally mounted in said cylinder having a vertical stem, and a die in the end of the stem, said dies being formed with a combined drill-bit shank gripping portion and a conical diverging tapering portion adapted to form an enlarged tapering head portion on drill-bits, an arm on said cylinder, a hammer piston and cylinder mounted on said arm, drill sharpening dolly reciprocally mounted to project into said cylinder in the reciprocal path of said piston, and arranged to face the conical end portion of said drill bit gripping dies, a valve chest on the cylinder, a system of fluid ports extending from said valve chest to said cylinder and dolly operating hammer piston cylinder, and a manually operated valve in said valve chest arranged to control the ports leading to said cylinders.

EDITORIAL.

BUENOS AYRES is to have an exposition extending from May to November next year in celebration of the centennial of the independence of the Argentine Republic. It should afford an excellent opportunity for North Americans to come into closer touch with our vigorous neighbor in the south.

PIPE LINES for carrying oil are exceedingly efficient means of transportation, but expensive to build. The directors of the Associated Oil Company have just authorized a bond issue of \$25,000,000, of which \$6,000,000 is to be expended in the construction of a new line from Coalinga to San Francisco bay, and of another from McKittrick across the mountains to Gaviota, on the Santa Barbara coast.

SOLLAR is a term applied in Australia to shovel boards. It is also widely used to designate any platform or resting place, particularly between levels in a shaft or in a ladder-way. The term is derived from middle English, but really goes back to the Latin *solarium*, a sunny place, originally an open gallery or balcony at the top of the house, exposed to the sun. Thus the same root-word that served the Roman taking his ease at home does duty for the Cornish miner resting in his climb up the shaft at the end of his day's work.

NEVADA COUNTY, long the banner district in the California gold belt, is once more dazzling the world with a phenomenal discovery of bonanza ore. Within three weeks the Sixteen to One mine is said to have produced \$400,000 in bullion. Rich shoots of ore have always been characteristic of the veins in the California slates, and in some cases the ore has continued to great depths, as in the Grass Valley mine, which is producing rich ore from 5000 feet below the outcrop. The recent discovery will attract deserved attention to this famous old county.

WITH THE COMPLETION June 26 of the period of mourning for the late Emperor and Empress Dowager of China, the Imperial Mints will resume work coining taels and the new dollars and fractional coins recently ordered. It is estimated the nineteen Mints will be kept busy for ten years to supply the coin already ordered by the Imperial Board of Commissioners of Finance and Commerce. The introduction of a national currency will be a more radical step than is generally appreciated, and will be highly experimental. At present each province issues its own coin, and inter-provincial exchange is hindered by the very general distrust of coins not locally current. Suspicion of the general Government is even more common. If the proposed Imperial coinage be successfully established it will

promote solidarity more, perhaps, than any other reform yet effected. Incidentally, a considerably increased demand for silver should result.

SWINDLERS find new opportunities every day. Even the Geological Survey occasionally suffers. The latest scheme was unearthed recently in Oakland, where a D. P. Coble has been sentenced for pretending to engage men for the Alaskan service. By means of a forged letter of authorization, he engaged some thirty men at "\$60 a month and found," going so far as to engage steamship berths to lend color to the scheme. Of course a deposit was required to guarantee that each man hired would work throughout the season. Fortunately, before the money was paid over the scheme was exposed, the wily schemer was arrested, and, after a prompt trial was given a sentence of eighteen months imprisonment. It may be a safeguard to remember that, in the words of the Director: "No person has ever been authorized to demand or receive money or any other consideration or promise, beyond that of faithful discharge of duty, from individuals seeking employment with the United States Geological Survey."

FERDINAND ZIRKEL has retired from the professorship of mineralogy and petrography after forty years of service. Beginning systematic work in petrography before the French had developed the principles of optical mineralogy, Zirkel's work goes back to the days of empirical observation. With singular generosity Zirkel extended to the younger Rosenbush a royal welcome when he worked out and applied the newer methods. To Americans, other than those who were Zirkel's students, he is well known through his writings. His volume on the microscopical petrography of the rocks collected by the Geological Survey of the Fortieth Parallel, contains the first exact description of the rocks of the Comstock lode. While the methods then available were crude and the difficulties which caused trouble were pathetic, the book will stand always as a monument, not only to the liberal attitude of Clarence King, but also to Professor Zirkel. To him in his retirement many American friends and admirers will extend greeting and good wishes.

RESERVOIR SITES in the western mountains are in demand. Mr. J. R. Garfield, while Secretary of the Interior, withdrew from entry considerable areas supposed to be suitable for this purpose. One of the first acts of the new Secretary, Mr. Richard A. Ballinger, was to throw these lands open to entry. Now at the direct instigation, it is stated, of Mr. Taft, the lands are a second time withdrawn, and the Geological Survey and Reclamation Service are ordered to make an examination to determine their exact character and value. It is well known that Mr. Roosevelt and his advisers perceived the danger of all such sites falling into the hands of a single company which would hold a monopoly of hydro-electric power throughout the West. It was this which led to the original withdrawal of the lands. The action of Mr. Taft in directing that they be again withdrawn and examined is significant of his

probable attitude toward such problems. It seems likely, however, that after the investigation is made the results will be transmitted to Congress, and the responsibility for action or inaction laid upon the legislative body, where it belongs.

Financial Prospects.

Wall Street's activity has set the wiseacres analyzing. They are trying to find a reason for the prevailing optimism. Even during the uncertainties of pending tariff revision a general strengthening of tone has been noted in the market. The Steel Corporation's report undoubtedly had much to do with this. While by maintaining prices without fixing them for a definite period the Corporation checked normal development, large production has been called for, aside from deliveries under old contracts, through the demand arising from repairs, maintenance, and necessary amelioration. In so complex a civilization as ours these constitute basis enough for a large volume of business. The common stock of the Steel Corporation is manifestly nearer important participation in earnings than ever before. This is due to the fact that the huge Gary plant has been built out of current profits, no bonds having been issued to make provision for the greatest output of steel the world has ever seen, at costs lower than ever before realized in this country or in Germany. Success gives contagion of hope. The spectacle of a corporation thriving despite hard times is exhilarating. Unfortunately, the other metals are not sharing this prosperity. Securities, however, have held their own. The spirit of optimism is in the air, and is making itself felt in a material way. The market revival is not a product of the 'boosters'. There is work in progress, and the Italian *padrone* has kept his watchful eye upon it and is bringing in workmen to meet this demand. We have come to regard the immigration statistics as another 'barometer' of trade, and a most mercurial one at that. The Italian peasant evidently keeps on hand a sum sufficient to return to the land of cheap macaroni and wine at the first sign of starvation here. His industrial generalship is distinguished by adherence to the time-honored wisdom of keeping open his line of retreat. The flight of the mis-named 'Diegos' was a conspicuous feature of the spring months of 1907. The merchants and manufacturers became suspicious of impending disaster only late in the summer. Now the tide has turned. Not only were there 113,038 arrivals in March, but the emigration for that month was below the normal. These are conclusive proofs that labor is in demand, and clearly indicates returning industrial activity. There has been a shrinkage of both exports and imports in nearly all the countries of the world, except France, which seems to have an irrepressible financial vitality. The reduction, however, is in the value, rather than in the amount of the commodities themselves. This renders deduction as to future probabilities less easy. The movement of raw material continues in a volume indicative of anticipated demand for manufactures on a normal basis. The prices of agricultural products have not receded from their former high level, and there has been a

notable increase in the price of grains. But little overproduction has taken place in any quarter, and a decided turn in the course of business, with the inauguration of new enterprises, would absorb the excess of metals now in store within so short a period as to cause immediate improvement in quotations. The existence of enormous quantities of idle money, as reflected in the low rates prevailing on both sides of the Atlantic, has already caused a movement toward new industrial investments. For a time fresh bond issues could lap up the surplus, these being largely issued to replace maturing short-time notes given by the railroads. New bonds are still welcome, but the tendency to reach into more speculative fields is manifest. We have already pointed out the readiness with which copper properties find a market, and the same is true regarding many other mineral deposits. Probably as many mines, which have reasonable expectation of success, have been floated during the last six months as during the same period in 1906. At bottom the demand for the product of the miner is one of the truest indicators of financial health.

Smelter Smoke.

For the sake of everyone to whom the continuance of operations at the Washoe smelter is of vital moment, we rejoice in the dismissal of the suit by Judge Hunt, putting an end to the famous litigation between the farmers of Deer Lodge valley and the Anaconda Copper Company. The suit is dismissed without prejudice to any action for damages on the part of the complainants. The Court found that the smelting company had applied nearly every remedy for the smoke-nuisance that offered hope of relief. On the legal side, the termination of the controversy creates an additional precedent sustaining public as against private right. The Western courts are divided on this question, and the conflicting judicial opinions are a detriment to normal development. A Supreme Court decision in a case involving this principle would be a distinct advantage. In the semi-arid regions the first call to the agriculturist has been the need of the mining community. The Far West has become more important for its agricultural than for its mineral resources, but it will be found that nearly every centre of such development has a mining enterprise as its nucleus.

Douglas, Arizona, affords a most interesting illustration of the way in which smelting has altered conditions so as to make them favor agriculture. Prior to the commencement of smelting there, farming had been impossible because of the wide range in temperature, the average diurnal variation being from a maximum of 92.6 to a minimum of 28.4, a change from day to night of 64.2 degrees Fahrenheit. Under such conditions plant life was limited to those desert orders which in the course of ages had developed resistance to such climatic severity. On the advent of the smelter, however, a pall of smoke was spread over the valley, serving as a reflector retaining the heat absorbed by the earth during the day, and reducing the range of variation to less than 30 degrees. The rich soil and abundant water of the valley invited agriculture, which has grown to large

proportions. It is a unique situation, for the farmer must accept whatever comes, sulphuric anhydride, arsenic, and the rest; an injunction shutting off the smoke would literally freeze him out. The case is also interesting as showing how agriculture follows the market created by the mineral industry, even when the possibility of growing crops depends absolutely upon the physical effect proceeding from the continuous operation of a smelting enterprise.

An Undemonstrated Process.

Ten years ago a group of financiers purchased the Santa Rita copper mines in New Mexico from Mrs. Phoebe A. Hearst for \$1,400,000 cash. This group included Albert C. Burrage, William Rockefeller, H. H. Rogers, Albert S. Bigelow, and Thomas W. Lawson. The property in question is extensive and shows copper at many points, but no high-grade orebodies of sufficient size to warrant important operations by the usual methods have been found. It is now being exploited by Mr. Lawson, who has resorted to the last expedient of the sharper—he now appears in the rôle of a new-process man. He claims to have participated in the invention of a wonderful process which is to save all the copper in the ore. In a remarkable volume of 250 pages he sets forth the disadvantages under which copper metallurgy is laboring, and calls attention to the losses, which he states at one-third of the original metal in the ore. If the losses in handling, concentration, and smelting be all included, the average would probably reach that amount. The largest occurs in the concentration. From twenty to thirty per cent of the metallic content is lost in that operation. The enormity of this well recognized defect in modern methods is impressively announced, and then follows the statement that the great problem has been solved. Mr. Lawson affirms that the new process is at work commercially, but that “the world at large knows nothing of its existence.” He even prophesies disaster for other copper producers so dire that the wonder is that a syndicate has not been formed to buy him out. The “readjustment of values in \$1,500,000,000 of copper securities” by reason of this revolutionary process is too stupendous—to be believed! Only the lesser troubles in life awaken anxiety and distress. Man is so constituted that he can face the really great calamities, even such as Lawson, with equanimity.

Part of the Lawsonian game consists in unexpected alliances. Certain recent flotations won because of great names in which the public had confidence. In this case the inventor of the new process is said to be Mr. Charles S. Bradley, the man who developed the first successful method for the production of aluminum. But there was no mystery hovering over those earlier efforts. The discovery was explained so that its details were understood by technical men. In the present case all the marks of the charlatan and humbug are present; there is a plant supposed to be in operation on a commercial scale, and the public is offered bonds convertible into stock; the process is supposed to be ready for installation in Grant county, New Mexico; and yet not one hint is given of the method pursued or the solvent used. This is the

same appeal to blind unquestioning faith that the new-process faker ever makes. 'You see me put in this ore; you see me take out this metal; what more do you need?' It recalls Wynn at Denver in 1901, with his use of Teller and Holdrege to give respectability to a wonderful secret process by which 'fine gold' was to be saved in quantity. Beam, Gage, Jernigan, and a host of names of similar inventors, come at once to mind.

But seriously, wonderful as are modern inventions, we are not in the Middle Ages, and it is no longer necessary for cunning craftsmen to guard trade secrets. These are the days when the great work of the world is done out in the open, under protection of law; when the light of science is turned upon the pretensions of discoveries; and he who slinks in darkness, evading investigation, however he may brag, may be considered to have found nothing that will bear the scrutiny of competent men.

Transportation and the Far East.

Adequate transportation is essential to commerce. No exchange of commodities can occur without means of shipment, and no steady trade can develop except where regular lines of transportation are available. Any complete system involves 'feeders', main-line haulage, and distributing lines. From the United States there are two routes; one by way of the Suez, and the other across the Pacific. The first has the advantage of dense local traffic but is long. The second has practically no local traffic but is short. The Suez route is cheaper, the trans-Pacific is quicker. Just how these advantages weigh against each other is shown by a recent shipment of mining machinery from Chicago to Siberia. The cost was approximately \$50 per ton, of which \$35 was absorbed by the rail-haul from Chicago to San Francisco. Similar machinery could have been sent from London by way of the Suez for \$7 per ton, but its transportation would have required months longer. This being a 'rush order' went by the quicker though more expensive route. It must be clear that regular trade cannot be created against this handicap.

Cheap ocean traffic is carried by tramp steamers, and by sail. These can, however, only be counted on where freight is abundant. Liners, sailing at an appointed time, whether loaded or empty, must be given some advantage if regular communication is to be established, and modern business more and more demands speedier dispatch. We prize regularity and promptness above mere cheapness. In doing so new trade they are essential. In the end they bring a recurrent cheapness.

The American railway system is a nearly perfect network of lines, well adapted to collect raw materials and manufactured articles and carry them to points of export. The centrality of the Western continent makes it a natural base of local traffic. They have been forced to offer low rates, and our rates are lower than those of any other country. The great fact that we could not find ships and companies to do the transportation on other terms, has given short hauls a further added stimulus to the Orient, a new

petition with the Suez route, making a division of rate with associated steamer lines which were under contract for regular sailings. In view of certain rulings of the Interstate Commerce Commission these tariffs have been withdrawn, and local rates to the Coast must now be paid. The result has been the withdrawal of ships and a heavy falling off in trade.

There are now eight lines carrying freight from Shanghai to American Pacific ports: two American, two American-owned but sailing under the British flag and carrying freight only, two Japanese, one Canadian, and one French line which carries freight only and sails from Europe to Asia and America on around-the-world trips. The trans-Pacific service is not only inadequate, but is largely foreign-owned. In addition, the distributing system of coastwise vessels and railway lines in the Orient is necessarily, and properly, foreign-owned. How important these lines are becoming is feebly appreciated. China is using the revenue from her existing railways to build new lines, and under competent native engineers, Chan Tien-yu, Yen Te-Cheng, and others, is making excellent progress. The Pekin-Kalgan line has been built through the most difficult pass, and by the end of the year will be completed. Surveys to the Siberian border are being made, and it is estimated that within six years the line will furnish not only direct communication between China and Mongolia, but a short-cut from Irkutsk to Peking. In the meantime the Japanese have re-built the South Manchurian railway, and with a full equipment of Pullman cars, and direct connection with the Chinese Eastern road at Changchun, it affords quick transit to Europe. The light railway built during the war from Antung to Mukden is being reconstructed, and will furnish within three years an adequate connection between the Korean and the Manchurian lines. Everywhere in the Orient railways and steamer lines are being established, and only in the Philippines do Americans take any part, though there is a temple in China dedicated to the memory of 'Ward the American' who not only put down the Taiping rebellion but also introduced over 100 American steamboats on the rivers of that country.

The opportunities in America for the use of capital, and the profits from local industries, are even yet so large that ship-building and operation, foreign railways and foreign concessions, have not been attractive to American investors. From a cold business standpoint there is no more direct profit to a rich and busy people in carrying their own exports to market than to a busy millionaire laboriously carrying his own trunk to the train. There might, however, be considerable indirect profit to either. It is possible that the millionaire might find it to his advantage to maintain at some loss a private baggage van, if it were necessary in order to assure prompt and satisfactory delivery of his baggage, and Americans may find it necessary by some means to control more lines of transportation to the Orient, if the full advantage of our short western route is to be realized. Custom tariffs are not the only means of discrimination, as the Mexican railways have recently shown.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

D. C. JACKLING is at New York.

ROBERT W. JONES is in Colombia.

LEWIS T. WRIGHT has left for London.

H. W. TURNER has been in Salt Lake City.

FRANCIS N. FLYNN is at Humboldt, Arizona.

E. H. GARTHWAITE has arrived from Salvador.

J. H. MACKENZIE leaves for New York on May 22.

RICHARD A. PARKER is on his way to eastern Sonora.

COLIN MCINTOSH has returned to Salt Lake City, Utah.

N. S. KELSEY will leave San Francisco for Alaska, May 22.

F. G. CLAPP is examining oil and gas territory in the East.

RALPH ARNOLD has returned to California from Washington, D. C.

FRANK KLEPETKO has moved his office to 42 Broadway, New York.

EDMUND B. KIRBY has returned to St. Louis from Gold field, Nevada.

JOHN MARCH, of the New Departure Mines, has returned to Dillon, Montana.

J. W. BRYANT, of the Tyee Copper Co., has returned to Victoria from Mexico.

R. H. TOLL is at Mancos, Colorado, examining properties in the La Plata mountains.

A. ROY HEISE has accepted a position with the Llanos Consolidated Co., at Boluda, Sonora.

J. M. RUFFNER, manager for the North Columbia Gold Mining Co., in the Atlin, B. C., district, has gone north for the season.

C. W. PURINGTON sailed for Japan Thursday. His address for the summer will be, Care Russo-Chinese Bank, Nikolaevsk, East Siberia.

GEORGE E. DRISCOLL, lately with the New York & Honduras Rosario Mining Co., will open an office at Sabana Grande, Honduras, Central America.

ARTHUR S. DWIGHT is consulting engineer for the Humboldt smelter, in Arizona. He is now at Humboldt, elaborating plans for resumption of operations.

W. H. STAYER, of Hemet, Cal., who recently had his arm broken in a runaway accident, is convalescent, and is studying the gem-formations of Riverside county.

PERCY E. BARBOUR has resigned the management of the Promontorios Mines, in Mexico, and has no connection whatever with the Clark Copper Co., which owns that property.

JOHN M. NICOL, until recently manager of the hydraulic department of the Joshua Hendy Iron Works, is consulting engineer to the Trinity River Mining Co., and is installing a new plant for them.

SIDNEY B. WILLIAMSON, Chief Division Engineer, Pacific Division, Panama Canal, is studying placer-mining methods in Trinity county and southern Oregon, in company with John M. Nicol, with a view to adopting this system of excavation for a section of the canal.

ASSIGNMENTS TO ALASKA for the present season's work of the United States Geological Survey are as follows: A. H. Brooks will remain in general charge and expects to make a personal trip from the Copper river to the Yukon and down to Nome. R. H. SARGENT will have general charge of the topographic work, and will make a detailed map of the Atatanaska coalfield. P. S. SMITH will make a reconnaissance from Nulato to the Seward Peninsula. L. M. PRINDLE will make surveys in the Yukon Tanana region. F. H. MORLEY and S. R. CAPES will work in the Copper River district. ADOLPH KNOPP will study the Berners Bay region. U. S. GRANT will study certain portions of the Kenai peninsula. G. C. MARTIN and D. C. WITHERSPOO will make a reconnaissance from Cook Inlet to Lake Iliamna. A. G. MADDERN will study the Coldfoot district on the Koyukuk.

General Mining News.

ALASKA.

(Special Correspondence).—A 3 stamp mill has been started at Fairbanks with the aid of brass bands and much enthusiasm. It is a home-made affair, built by Brumbaugh, Hamilton & Kellogg, and designed to treat the quartz ores of the Tanana valley. To this mill Lucien B. Rhoads and W. C. Hall have sent a 1740-lb. sample of the ore from their Free Gold quartz claim, and in 10 hr. a yield of \$137 was obtained with no further saving apparatus than a short length copper amalgamating plate. Rhoads and Hall located this claim last September on Bedrock creek, a tributary of Cleary creek, and sunk a shaft 50 ft. deep on four small stringers which lie within a few feet of each other. Trenches have exposed the veins on the surface for some thing over 300 feet.

Fairbanks, April 16.

ARIZONA.

COCHISE COUNTY.

The Copper Queen is now shipping 35 cars of ore to its smelter at Douglas and four cars of sulphides to the Old Dominion at Globe. These sulphides are obtained from the Holbrook shaft and run 45% sulphur. All the ore from the Copper Queen properties, with the exception of the Lowell, is now being handled through the Sacramento shaft.—The April output of the Calumet & Arizona and Superior & Pittsburg will be slightly less than that of last month, which was 4,500,000 lb.—The Junction property of the Superior & Pittsburg is shipping an average of 16 cars a week, the Hoatson 48, and the Cole 36, a total of 100 cars, or about 4500 tons, weekly. The recent strike at the Junction on the 1200-ft. level has shown up at present about fifty feet of oxides, assaying between 5 and 7% copper. The sulphide body in the southwest drift on the 1400-ft. level continues to average 15% copper.—The Wolverine & Arizona, for the first time in its five years of existence, has made a shipment, which consisted of 500 tons of oxide ore averaging 11% copper, which included about all the ore on the dump which has been extracted during the process of development work.

GILA COUNTY.

J. J. Shaw, manager for the Mazatzal Copper Co., reports the new adit to be in about 225 ft. and expects to reach the vein in about 25 ft. more. The company owns about 700 acres altogether, with the mines about 9 miles from Payson, which is 80 miles northwest of Globe, the nearest railroad point.—News from the Inspiration Copper Mine property states that the sulphide orebody is developing very well. In the shaft 800 ft. from the Miami lines, between the depth of 100 and 125 ft. the ore averages 21½% copper.

A branch of the American Mining Congress has been formed in Globe, under the presidency of J. D. Coplen, to stimulate legitimate mining in the district and to prevent exploitation by fraudulent promoters. The other officers of the local branch are F. A. Woodward, M. C. McCarthy, Louis A. Wright, A. G. Smith, and J. K. Satchell.

MOHAVE COUNTY.

Great activity prevails in the San Francisco range, bordering the Colorado river between Eldorado canyon and Parker, in Yuma county. About midway along this range is the Goldroad mine, where quantities of \$10 ore are blocked out. The company is erecting a 60-stamp mill, and expects to have it ready by July 15. The power line from the Deere Power Co.'s station in Kingman to Goldroad, a distance of 25 miles, is now being constructed. At the Tom Reed mine, near the Goldroad, a 10-stamp mill is being erected and will use the same power line. The company is at present running the old 10-stamp mill, and is reported to be working on a 20 ft. vein of \$50 ore. Three miles from Kingman the Bimetallie Gold Mine Co. is developing a property formerly known as the McGuire mine. It consists of a lava capped hill with a vein, carrying free gold worth about \$8 per ton. A 10-stamp mill, with concentrators, has been installed, and has now been in operation for

three months. Further additions to the present plant are intended.—The Expansion Mining Co. was organized about a year ago, by Charles J. Hutchinson of Seattle, Wash., and is operating a mine at Union Pass, 25 miles west of Kingman. A shaft 170 ft. deep has struck good ore, and the company is now intending to put up a stamp-mill.

YAVAPAI COUNTY.

The Yavapai Mining & Development Co. has just completed a well nearly 2000 ft. deep at Del Rio, prospecting for oil. At a depth of 1888 ft. oil-sand was struck, which proved to have a thickness of 90 ft. The sand is thoroughly saturated with oil which is pronounced by experts to be a high-grade paraffine oil. Another well is to be started at once, according to J. A. Gilbert, secretary and director of the company.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence).—Owing to a disagreement between the operators and miners over the new eight-hour law, the men employed at the Argonaut and Zella mines at Jackson, the Bunker Hill and Fremont at Amador City, and the Campo Seco mines and smelter at Campo Seco have gone on strike. The men demand that eight hours shall include the time of going and coming to work, while the operators insist that eight hours of actual work must be performed. The Argonaut employs 150 men, the Zella 130, the Bunker Hill and Fremont 300, and the Campo Seco 100. The Kennedy is unaffected at present. The management of the Campo Seco properties announces that only enough ore is on hand to run the smelter about three days, and that if the men do not return to work before this time the smelter and mine will be permanently closed down. It is stated the company has not been making more than expenses for several months and will not stand for a reduction of working time. This will throw out the 150 men employed on the surface. A conference will probably be held soon, as the miners have named a committee to meet the operators of the various properties affected.—Operations have been resumed at the Keystone mine with a small crew. The mine has been unwatered and work will be done in the lower workings. J. McDonald is in charge.—A cyanide plant is being installed at the Defender.—The Hambric lease on Amador Queen shipped 1200 lb. of ore last week to the Selby smelter. The shipment was valued at \$1200.—The damage recently done to the shaft at the Kennedy by a runaway load of timbers has been repaired and all the men are back at work. The mill has been idle for several days as a result of the exhaustion of ore supply.

Jackson, May 10.

CALAVERAS COUNTY.

S. R. Fox has leased the Hagerman gravel mine, situated about three miles north of San Andreas, and will test the ground to ascertain if he can work it by dredging.—W. H. Brown and associates have a two-year bond on the Early Bird property, which they have been operating during the past two months. The 10-stamp mill is kept running steadily with a force of about twenty men on the pay-roll.

ELDORADO COUNTY.

The El Dorado-Placer Dredging Co. has been incorporated at Tucson, Arizona, to work the auriferous channels of the American river, which separates the counties of Placer and Eldorado. The directors include Henry Fuller, William J. Variel, M. E. Williams, B. F. Bledsoe, and others.

NEVADA COUNTY.

A scheme is being elaborated to renew work at the famous placers of North Bloomfield. Under the town lies a deposit that has never been worked, and which is believed to be just as valuable as most that has previously been turned over. Property owners are now willing to allow their houses to be undermined, and to receive a percentage of the profits obtained therefrom. The work of undermining can be done without inconvenience to the inhabitants.

PLUMAS COUNTY.

The Spring Garden tunnel of the Western Pacific railway, near Quincy, has been completed. It is 7000 ft. long, while

another, 6400 ft. long, known as the Chilcoot tunnel, is very nearly ready for the rails. The construction of this new road has required 45,525 ft. of tunnel in its total length of 927 miles, and has thereby enabled three mountain ranges to be crossed with a maximum gradient of 1%. The summit to be crossed by the new railroad is 2000 ft. lower than that by which the Southern Pacific crosses the Sierras, being only 5018 ft. at the Beckwith pass.

SANTA BARBARA COUNTY.

The Union Oil Co. has a dry well at Lompoc which is 4450 ft. deep. Another is being sunk at Rosemary on its Brashear lease, that is now 5117 ft. deep, with no indication of oil yet found. It is the deepest well in California, and one of the deepest in the world. The well has 12½-in. casing to 1048 ft., 10 to 2902, 8¼ to 3908, and 6¾ to 5098. Sinking will continue as far as 6000 ft. if necessary, although work has been progressing continually for two years.

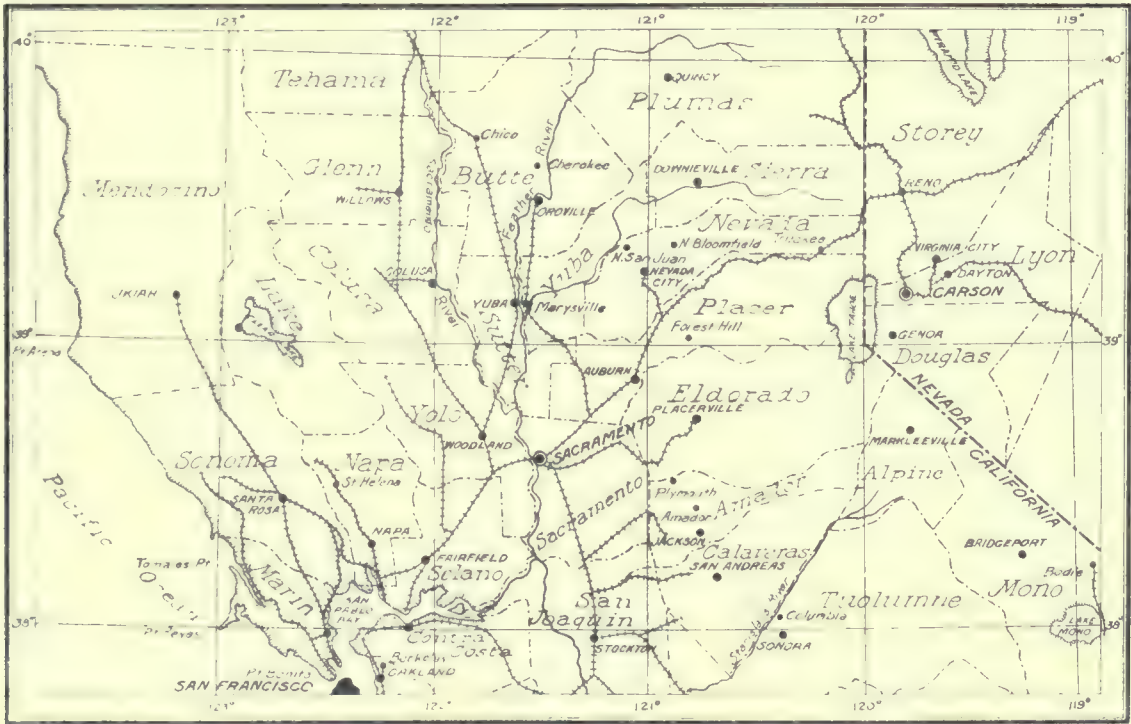

SHASTA COUNTY.

The Lucky Spot mine has been incorporated to work the old placer claim of that name, near Ingot, which was worked with much profit in the past. Work on this mine was de-

now 10 levels in the mine, with the lowest at 800 ft. Milling is effected by amalgamation and concentration, nearly 80% being saved by the former process. C. S. Verrill is manager and C. L. Pierce superintendent. The former will shortly leave for Boise, Idaho, to take charge of a mine.—Good development is being made at the Black Oak mine, which is about 1300 ft. deep. A total extraction of 96% is being made from the general run of ore, which varies between \$6 and \$15 per ton. The millman, S. A. Knapp, keeps 20 stamps at work all the time, and others when the ore supply admits. Roger C. Knox is general superintendent.—The Crystalline and Alabama mines, near the Harvard mine, at Jamestown, have been leased for some time to H. Leighton and V. Farmer, who have developed sufficient ore to start their mill. This will be done as soon as adequate water supply is available.—The Esmeralda and East Esmeralda mines, at Tuolumne, have recently been bonded by J. S. Gasper, George Medelin, and O. H. Green, who are advancing the adit along the vein, and are now in 175 feet.

YUBA COUNTY.

By the first of July an additional battery of 10 stamps

Map of Central California.

layed for many years, the property being in litigation. The courts decided recently in favor of the miners, against the Southern Pacific Co. Now that a favorable decision has been rendered, operations will begin at once.

SIERRA COUNTY.

The Sixteen-to-One mine, at Alleghany, continues to produce ore of phenomenal richness. It is indeed one of the most remarkable pockets ever discovered in the region, as ore to the value of fully \$300,000 has now been obtained in a single drift 5 by 7 ft. in size, without any stoping. E. H. Wilson, the principal owner, has 10 men at work.

TRINITY COUNTY.

R H Elliott is engaged in prospecting an extensive area of gravel around Trinity Center, to ascertain if it is suitable for dredging. He will soon have a Keystone drill on the ground to accelerate his investigation.—At the Birdie M. mine H. S. Nonemaker has opened up a 3-ft. vein of rich ore, assaying high in gold and carrying some silver. The mine is situated in the New River mining district, about 1½ miles from Quimby postoffice.

TUOLUMNE COUNTY.

The Bagdad-Chase mine, near Soulsbyville, is employing about 50 men underground and on the surface. There are

will be installed in the mill of the California Mother Lode Mining Co., making 20 stamps in all. The plant will then be one of the biggest in the region. The development work has opened up sufficient ore to keep the 20 stamps dropping constantly. A day and night shift will be worked. The mill will then have a capacity of 100 tons per 24 hours. Walter de Varila is in charge of operations.

COLORADO.

EAGLE COUNTY.

The mill of the Eagle Mining & Milling Co., near Redcliff, designed to handle the low-grade ore of the Iron Mask mine, is rapidly nearing completion, and will, it is expected, be in operation by the first of June. The mill will have a capacity of 100 tons per day, the method adopted being concentration.—The new aerial tramway of the Rocky Point mine is now ready, and will transport about 50 tons per day to the shipping point. There are now 30 miners employed. The lessees, Dismant Bros., Little & Baldwin, have been experimenting on their low-grade ore to find an efficient method of milling.

EL PASO COUNTY.

The Golden Cycle Mining Co. has purchased the Pike's Peak Fuel Co., to the north of Colorado Springs. The com-

pany will begin at once to erect a power plant on the site of the Park View coal mine, and to furnish power for the company's mill at Colorado City. It is expected later to furnish coal for the Golden Cycle mine at Cripple Creek.

GILPIN COUNTY.

Two cars of concentrates have been loaded at the Rollinsville depot of the Moffat road for shipment to the Argo smelters, by the Perigo and Smuggler mills. Two carloads of machinery have also been received for the Tungsten Mining & Milling Co., which has been hauled to that camp for installation in the new mill.—A number of men are making preparations for working in Nevada gulch during the season when the water supply is plentiful, and several sluice-boxes are already in evidence.—The German Gold & Uranium Mining Co. has a force of 11 men at work in its German mine, in the Nevada district, and has begun to install its new steam engine in the shaft-house.—The gold production of Gilpin county in 1908 was nearly \$1,100,000, or fifth in order of the gold producers of Colorado.

TELLER COUNTY.

The production of the Cripple Creek district for the month of April has totaled 59,700 tons, of the gross bullion value of \$1,351,375. As compared with the preceding month there is a decrease of \$31,145, due to the shorter month, and to the fact that returns could not be obtained from the new mill of the Stratton's Independence, in the absence of Philip Argall. This mill has so far only worked on a small scale, the nominal capacity being 300 tons per day.—Measurements taken by the engineer, T. R. Countryman, at the Cripple Creek Drainage tunnel show a total gain for the month of 986 ft., making an addition to the records in speed of driving already accomplished. The Portal heading was driven 316 ft., the north and south headings from the Intermediate shaft, 387 and 283 ft., respectively, giving a total distance driven to date of 8424 ft., or more than one-half required to tap the main vein on Beacon hill. In about six weeks connection will be made between the Intermediate shaft and the Portal.

An important discovery has been made on the 500-ft. level of the Gold Coin shaft of the Granite Gold Mining Co., situated within the city of Victor, by Richard Little and his associate lessees. By a cross-cut 300 ft. east of the main vein, a new orebody has been exposed, heretofore undeveloped. It has been named the 'Black Canon' lode by the superintendent, Dan McCarthy, on account of the dark color of the walls. Since the cessation of pumping operations at the Strong mine, the water in the Gold Coin shaft has risen to a point about 60 ft. above the station on the 1000-ft. level, submerging the station pump. All work in the mine is being done by lessees, there now being no men on company account.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence). Decreases in profits ranging from 65% on the Hecla to 40% on the Federal properties are reported in statements by the various mining companies to the assessor of Shoshone county. In consequence of this decrease the assessed valuation will be reduced from \$10,000,000 in 1908 to about \$9,000,000 for this year. Several of the big producers were closed from two to five months in 1908. The Hecla was shut down about five months, the Last Chance almost three months, and the Tiger Poorman and the Morning mines were closed for a longer period. The Tiger Poorman showed a loss and was dismantled. Late the Morning property was operated at a small net profit. The Beacon Hill & Sullivan Mining & Concentrating Co. reported net profits of \$122,000, while the gross amount of \$1,400,000. The mine was worth more than \$7,000,000. The Hecla mine at Blackfoot reported profit as \$38,000, and a net value of \$1,100,000. The Hecla mine at Coeur d'Alene reported a net profit of \$150,000 and \$750,000 respectively. Net profits of the other mines are as follows: St. George and North at same place as Last Chance at Wallace \$24,000. Morning mine \$75,800, while the net profit of the Tiger Poorman & Beacon mines is \$118,800. The decrease in the county reported will be made in this

year by the advent of the Chicago, Milwaukee & Puget Sound, and the Idaho Northern railway companies, which will be assessed for the first time.

Wallace, May 8.

(Special Correspondence).—At a special meeting of the stockholders of the Montana Standard Mining Co., just held in Wallace, it was agreed to increase the capital by \$500,000, to purchase a mill for the mine. A large amount of ore has been blocked out and a number of shipments have already been made.—The long adit driven on the property of the Alma Mining Co., near Mullan, has encountered the vein, and about 12 ft. of low-grade ore has been exposed, the average value of which is between \$5 and \$6.—A strike of 5 ft. of clean shipping galena ore has been made on the property of the Orofino Mining Co., recently bonded by Patrick Burke of this city. The strike was made at a depth of 350 ft. In addition to the shipping ore, a large amount of milling ore has been exposed, the full extent of which has not yet been ascertained. The strike has created quite a little excitement in the Murray district.—Nearly \$3000 has been promised by the business and mining men of the city of Wallace to provide a suitable ore display at the Alaska-Yukon-Pacific Exposition. The mine owners are doing everything possible to get up a display worthy of the region. At the same time, the Wallace Board of Trade will make a strong attempt to have visitors from the East pass through the Coeur d'Alene on their way to the Fair.—The 6000-ft. adit which was started some time ago on the property of the Iron Mountain Mining Co. has now been completed, and Patrick McElmeel, the superintendent, is engaged in installing two boilers and a 15-drill Ingersoll-Rand compressor. The property was closed down some years ago by order of the State Mining Inspector on account of the fact that there was only one shaft, the law requiring two in case of accident. The ore will be mined through the long adit and treated in the same manner as in the other big mines of the district.—Arrangements are being made for a resumption of work at the Charles Dickens mine, on Moon creek. It is intended to sink about 300 ft. Arrangements have been made with the O. R. & N. company to construct a spur to the mouth of Moon creek, and when this is done a carload of concentrate now at the mill will be shipped. The property was recently acquired by the Idaho-Knickerbocker Mines Co.—A fire which broke out at the end of last week destroyed the plant of the Shoshone Concentrating Co. The damage is said to have been about \$25,000, of which \$15,000 was covered by insurance. The mill was built to treat the tailing of the Last Chance mine at Wardner, and preparations were being made for resumption of work at the time the fire took place. The cause of the fire is unknown.

Wallace, May 8.

MICHIGAN.

The Copper Range Railroad Co. has let a contract to construct a branch line to Point Mills, where will be erected a new dynamite factory by the E. I. Du Pont de Nemours Powder Co. Point Mills is east of Dollar bay, and north of the Franklin and Centennial stamp-mills. E. K. O'Brien, the construction engineer for the company, is on the ground and will have work started as soon as the branch line is completed.—Isle Royale's new hoisting and compressor plant at the No. 6 shaft is now in regular commission. The smaller 2½-ton skip has been replaced by a 7½-ton skip, and a second will be installed as soon as the skipway in the second compartment of the shaft can be made ready for the heavier duty. The shaft has now been sunk 75 ft. below the seventh level. The average copper content of the 'rock' milled shows a gradual gain since the first of the year, the higher average being due to the shipments from the Isle Royale lode in the No. 4, 5, and 6 shafts. The mill is treating between 900 and 1000 tons of rock daily, or about 27,000 tons monthly.

MONTANA.

BEAVERHEAD COUNTY.

A tunnel 1500 ft. long will be driven by the Calumet Hecla Mining Co. at its Dark Horse claims southwest of

Dillon. Superintendent Lanyon estimates that a saving of \$20 per ton may be effected by giving this outlet from the mine to a railroad siding at Baker.—Machinery has arrived in Dillon for the North Dakota Mining Co.'s cyanide plant, to be erected at the company's mine near Polaris. The plant will have a daily capacity of 25 tons. The machinery will be freighted up to the mine and installed just as soon as the roads will permit.

NEVADA.

(CHURCHILL COUNTY.)

George Wingfield and Eastern associates have taken an option on 600,000 shares of the stock of the Nevada Hills Mining Co. at \$1.25 per share. The deal involves \$750,000. The mine will be consolidated with the Fairview Eagle, its neighbor, and a large mill erected. The stock under option was held by W. W. Rice, of Salt Lake, James R. Davis, W. H. Clark, of Salt Lake, James Farrell, John A. Kirby, J. T. Hodson, and W. H. Webber.

(CLARK COUNTY)

The 10-stamp mill of the Pompeii Mining & Milling Co., near Searchlight, has been started, under the management of Matt Hoveck. It was manufactured by the Risdon Iron Works. Hoveck has lately found high-grade ore in a raise east of the shaft, but considers that \$8 ore will yield a substantial profit in the mill.

(ESMERALDA COUNTY)

(Special Correspondence).—The Marigold lease on Rawhide Coalition has uncovered a 10-in. streak of rich ore in the south drift from the 160-ft. level. Assays are said to run about \$500 per ton, with portions running as high as \$1500 per ton. In the north drift the vein, about 1 ft. wide, averages \$400 per ton. Work is being rapidly pushed at both points and the new shoot has been uncovered for several feet.—The Grutt Mining Co. is sinking on a 2-ft. vein reported to run about \$300 per ton. Values continue with depth and the lease expects to make an early shipment.—In the bottom of the new shaft of the Miners' lease a 4-ft. body of fair-grade ore is showing.—Despite the fact that a large number of lessees are operating and that several are shipping high-grade ore, Rawhide continues very quiet, in marked contrast to the rush prevailing a year ago. Indications are promising for making several good mines, but the future of the camp depends on deep developments in the Coalition and Queen properties.—The Polaris claim has been purchased by a syndicate of Goldfield men and has been renamed the Big Six. Six hundred feet of the claim lies in the gulch which is attracting wide attention from placer miners. A 15-hp. hoist has been ordered, also a small pumping plant. Active work has commenced.—The Planetaiz lease on Union No. 9 has opened a vein running from a few inches to 2 ft. in width from the surface to the 291 ft. level. Drifts are being run on the 150 and 235 ft. levels with the ore extracted milling about \$10 per ton.

Rawhide, May 7.

John Miller, one of the chief owners of the Lucky Boy and Alamo group of claims in the Hawthorne district, confirms the report that a 30 days' option on these properties has been given to the United States Smelting & Refining Co. in the sum of \$1,500,000, and says that the first payment must be made by May 25 and the balance in two months thereafter. He says he is confident that the sale will go through, but will not be disappointed should the deal fail, as he considers that much more money than the stipulated price can be taken out of the ground within a year.—It is reported from Blair that the Lookout mine and mill, six miles from Oakes, which fell into the hands of the Risdon Iron Works at San Francisco, is being sold at a great discount, and is not likely to change hands.—Forty additional 50-ton capacity steel cars for handling ore were delivered to the Tonopah & Goldfield Railroad at Goldfield, to keep up with the demand for cars to haul ore from Nevada districts.

(EYRE COUNTY)

(Special Correspondence).—At a meeting of the officials of the

at the Nemo Extension near Manhattan is said to be in a thin bed of gravel averaging \$30 to \$50 per yard. It is expected to strike the bedrock at a depth of 55 ft.—The recent clean-up of the placers of the McDonald lease is said to have run nearly \$30 per cubic yard. This claim is centrally located and is surrounded by other leases, all of which are steadily working.—A section of the Wolf Tone Extension has been sold to J. R. Davis, A. A. Bissell, T. D. Murphy, and other Goldfielders for a consideration reported to be \$25,000. Several nuggets have been found, together with some coarse gold, and the property will be actively worked for its placer wealth.—It should be remembered by outside investors who are not familiar with conditions that placer mining at Manhattan presents some drawbacks. It is not hydraulic or placer mining as commonly understood, but involves a complex system of handling several times, in addition to extended digging and washing. Costs are thus higher than in other districts, and many miners who have been in the Klondike and other placer fields do not think that the Manhattan placers are as valuable as recent reports would indicate. Many of them, after careful examination, have refused to invest, and predict that the placers will fall short of anticipations. While Tonopah and Goldfield mining men have every confidence in the placers, it should be remembered that Nevada miners have had little experience with this kind of mining, and are apt to over-rate indications.

Manhattan, May 7.

At a meeting of the officials of the Tonopah Extension Mining Co., held in New York, it was determined to build a mill immediately, and John G. Kirchen, general manager, was empowered to give the necessary orders. The new mill will contain 30 stamps, together with a cyaniding plant, having a capacity of 120 tons a day. The building will be put up large enough to accommodate 40 stamps, so that 10 additional may be hung at any time. The method of treatment will follow closely along the lines of the Montana, but the entire plant will be housed under one roof. The location of the new mill will be about 100 ft. west of the ore dump, on the south side of the Tonopah & Goldfield railroad tracks.—The dividend of the MacNamara Mining Co. of Tonopah for the present month has been passed owing to the necessity of using the money to continue sinking the shaft, which is down past the 775-ft. level. The shipments for the past week aggregated six cars of ore, which were sent to the Western Ore Purchasing Co. at Millers. The mine shows no important change in condition. Development of the new vein on the 150 ft. level of the Spring mine at Round Mountain is being continued by M. J. Kiely, who has a total of 22 men employed on the property. Milling is being done by one Huntington.—There is great activity at the Jefferson mine, near Round Mountain, where James McDonald is constructing a mill comprising crushers and Grampner rolls, Pinder concentrators, and 18 redwood cyanide vats. The principal motive power will be obtained from a Webster engine.

(WHITE PINE COUNTY)

The output of the Nevada Consolidated Copper Co. in April amounted to 2,609,975 lb. of copper, the largest on record. The Cumberland Ely produced in the same month 1,724,784 lb., making a total for the two companies of 4,334,759, or at the rate of more than 20,000,000 per annum. The new reverberatory furnace will be completed in 60 days and the fourth unit of the Steptoe smelter will be finished in 90 days. When these improvements are completed the plant will have a capacity of 75,000,000 lb. of copper per year.

SOUTH DAKOTA.

(LAWRENCE COUNTY)

A. Allen C. Lee, president of the Robert W. Hunt Co. of Chicago, who is in charge of the building operations at the Hercules plant at Goldfield, reports that construction of the 220-ton steam engine is well started. The Hercules Mining Co. owns some 500 acres of mineral-bearing land. A large crushing at the mine the ore will be conveyed to the mill at Goldfield. The Hercules plant is being built on a site where the ore is crushed and then taken through a series of

screen, when two Dorr classifiers will separate the slime and sand. A pair of 5 by 22 ft. Allis-Chalmers tube-mills will further reduce the sand, passing it to hydraulic cone classifiers. The coarse product is then to be returned to the Dorr, while the fine joins the slime. The entire volume of ore will at this stage be reduced to the consistence of slime, and be passed to two Pachuca, or Brown, tanks, 15 ft. diam. and 45 ft. high, where agitation is effected by compressed air. A Butters filter will subsequently separate the solution from the leached slime.

WASHINGTON.

KING COUNTY.

The Seattle Cascade Mining Co. is developing a property close to Berlin, on which 500 ft. of work has been done, opening a vein of galena and silver ore from 18 in. to 4 ft. wide. Frank Jagerson, R. T. Dixon, and Frank Winquist are among the interested parties, and state that they will install a crusher, Chilean mill, and concentrating tables for

Brown, or Pachuca, Agitating Tanks.

treating the ore. The property is four miles from the rail road.—The Horseshoe Mining Co., of Seattle, has done 1250 ft. of development work on its two groups of claims, situated in Mt. Defiance range, between the middle and south forks of the Snoqualmie river, and six miles from a branch of the Northern Pacific railroad. Several veins have been opened, carrying copper, gold, and silver. The company has spent \$1000 on buildings, \$1400 for machinery and tools, and \$1000 on road and trail. Swan Hansen is in charge of the work.

SKAGIT COUNTY.

The Skagit Queen, situated 40 miles from Marblemount, on Thunder creek, is resuming work on a cross-cut to intersect three parallel lodes embraced in the property. This cross-cut was driven 270 ft. last year and they expect to cut the first lode by driving 400 ft. farther. The company has installed a small air-compressor, operated by electric power, the generator being driven by a Pelton water-wheel. With this equipment air-drills were operated last year. Since then a larger installation has been made, said to consist of a 48 in. Pelton wheel, operating under 750 ft. head of water, carried by a 16 in. steel pipe 1500 ft. long.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The continued strike of the coal miners in southern Alberta has resulted in the closing down of the property of the British Columbia Copper Co., throwing several hundred men out of work. The mine was closed down a few days ago, with the exception of a small force on special development work; the smelter closing as soon as things could be got in proper form. There is practically no change in the situation of the striking coal miners, and it is difficult to say just when a settlement will be made. It is estimated this will cost the copper company between \$9000 and \$10,000 per month for maintenance of openings, pumping, general supervision, etc.—The Snowshoe mine continues to send out about 2200 tons of ore to the Trail smelter. The total shipments from the Boundary district for the week ending May 1 amounted to 31,812 tons, the Granby shipments being heavier than they have been for some weeks.—By a decree of the Supreme Court the property of the Dominion Copper Co. at Boundary Falls and Phoenix will be sold on May 28 at Vancouver. The reorganization committee claims to have had \$518,000 out of \$800,000 outstanding bonds, deposited with them.—The first payment has been made on the bond which A. S. Locke and associates, of Winnipeg, have on the Donald Copper property, near Midway. J. C. Haas of Spokane has charge of the work and expects to develop a good body of gold-copper ore.—The shaft on the Golden Zone property is being driven at the rate of about 12 ft. per week. It has now reached a depth of 95 ft., and some of the best ore found on the property has been taken from the bottom of the shaft.

Phoenix, May 6.

MEXICO.

HIDALGO.

There is a severe drought of drinking water at Pachuca, but so far it has caused no reduction in activity in the mines or milling plants, as the companies use nearly all their water repeatedly.—The Loreto mill of the Cia. Real del Monte y Pachuca is milling 400 tons per day of raw ore that assays 1100 gm. in silver and 6 gm. in gold per ton. The Guerrero mill, belonging to the same company, but situated beyond the camp of Real del Monte, is putting through approximately 270 tons daily of ore that assays 600 gm. silver and 3 gm. gold per ton. The Guadalupe mill, using the old patio process, is treating good tonnages of ore, coming mostly from the Santa Gertrudis camp. La Union and La Paz mills are working slightly under full capacity, while the same is true of the two San Francisco mills which are treating custom ores only.

The Pachuca river works, operated by the Blaisdell Cocositlan Syndicate, is putting through a good tonnage of the old tailings which resulted from milling operations of the past. Considerable construction work is being done by this company in order to increase the tonnage treated. Within three months the capacity of the present plant will have been tripled.—An abundance of milling ore with cheap electric power, which is supplied to the mines and mill at approximately \$96 per horse-power-year, are the main factors to which Pachuca's present condition of prosperity are due.

JALISCO.

At the El Favor mine, in the Hostotipaquillo district, all machinery and materials are on the ground, and satisfactory progress is being made in the erection of the 100-ton mill. It will be ready by the time electric power can be delivered, early in October. Makeever Bros. consider it advisable to increase the milling capacity, as they have sufficient ore available to treat 500 tons per day for many years.

OCEANIA.

FILIP ISLANDS.

Discoveries of mineral veins are reported from Suva, in these islands, and some Australian miners are on the ground examining them. Copper, gold, and silver are said to occur, but satisfactory arrangements have yet to be made with the local government to permit mining development.

Special Correspondence.

LONDON.

Mining Schools.—South Crofty Tin Mine.—Mountain Copper.

The three mining schools in Cornwall are to be amalgamated under the name School of Metalliferous Mining. Of the three schools, that of Camborne is of course by far the best known. It was founded in 1883, though classes were started six years earlier. In fact, courses of lectures were started in 1859, under the auspices of the Miners' Association of Cornwall. The first mining school in Cornwall was founded at Truro, by Sir Charles Lemon, even earlier, but did not last long. The establishment of the classes of the Miners' Association was due largely to the efforts of Robert Hunt, and it is interesting to record that Richard Pearce was one of the earliest lecturers. The present Camborne Mining School specializes on metalliferous mining and ore-dressing, rather than metallurgy, and in J. J. Beringer and J. G. Lawn it has two professors whose names are known the world over. The other schools are the Redruth School of Mines and the Penzance Mining School, both of which have done excellent work on a smaller scale. For some years there has been a feeling that these schools should be under one head, but there have been practical difficulties in the way. The recent Education Act provided a means of co-ordinating the educational system of the country generally, and steps can now be taken. The Board of Education has evolved a plan which has received general approval. The governing body of the School of Metalliferous Mining will consist of 22 members, of whom 14 will be nominated by the Cornwall County Council, and of the remainder 2 will be nominated by the Imperial College of Science & Technology, and 1 each by the Institution of Mining & Metallurgy, the Institution of Mining Engineers, the Iron & Steel Institute, and the Institutions of Civil, Mechanical, and Electrical Engineers. The Cornwall County Council is the local educational authority, and the Governors nominated by it will include several of the present committee of the Camborne school—Messrs. Holman, Pearce, Pendarves, Vivian, Thomas, and others. With this consolidation of mining education in Cornwall, it is probable that some arrangement will be made for co-operation between the School of Metalliferous Mining and the Imperial College of Science & Technology, otherwise the Royal School of Mines.

The directors of the South Crofty mine, in Cornwall, announce that "the ore left standing in the upper levels by the former workings, though of a very fair average grade, does not come up to the value the Board was led to believe." This is only too common in connection with Cornish mining. In the old days no records were kept. When re-opening the mines began everything depended on hearsay. A Cornishman is an optimist, so that the accounts of unworked mineral wealth are apt to become unconsciously exaggerated. To some extent the newcomers are to blame for not making thorough examinations for themselves, though, to do them justice, they are often dissuaded from doing so by the argument that it was an unnecessary expense. I have heard of more than one case where the demand of the outside engineer for a thorough sampling of the mine has led to considerable local friction. The South Crofty is a tin mine in the heart of the Camborne district, and adjoins Dolcoath. Its ores contain wolfram and arsenic and are therefore not so pure as those of Dolcoath. Three years ago the Allen Meyerstein group in London took control and invited a large amount of capital. A new main shaft, now 1200 ft. deep, was sunk. Modern machinery was erected, with a dressing plant now consisting of 60 heads of California stamps, with vanners, Buss tables, and magnetic separators. The ore is very hard, and the stamps, crushing to 30 mesh, treat only 4750 tons per month, or slightly over 2½ tons per day per head. During 1908 only 40 stamps were running most of the year, the last 20 being erected within the year. The amount treated was 41,628 tons, and the yield was 442 tons of tin concentrate, sold for

£34,162; 96 tons of wolfram, worth £8676; and 395 tons of arsenic, worth £3287. The recovery was 23.8 lb. of tin concentrate and 5.18 lb. of wolfram per ton. The cash value recovered per ton of ore was £1 2s. 1d., and the working cost £1 0s. 10d., leaving a margin of 1s. 3d. per ton. The cost does not include shaft-sinking and equipment, which are charged to capital, or administration expenses and depreciation, so that under present circumstances the mine is not yielding a profit. It is to some extent a matter of congratulation that no loss is being made, as is unfortunately true at some adjacent mines. It has been decided that, owing to the comparatively low content of the ore left in the upper levels, it is best to try the lower levels, which are at present under water. Accordingly the new shaft is being sunk another 150 ft., and pumps are being installed to reduce the water to that extent. The success at Dolcoath in developing ore at 3000 ft. should stimulate the directors of South Crofty to go even lower than present plans contemplate.

In writing about the Mountain Copper Co. a year ago I mentioned that the directors intended to go slowly with regard to the output of copper until they could market the remaining reserves at a higher price. Accordingly, during 1908 the output of copper from the better class ore has been restricted as much as possible, and the chief source of production has been the poorer ores which carry just sufficient copper to act as a carrier for the precious metals contained in the purchased fluxing ores. These ores are high in sulphur, and are used also for the production of acid. Unfortunately, the demand for acid has been very small recently, owing to the general depression in business. The output of copper during 1908 was 1838 tons, as compared with 3407 tons in 1907, and 2854 tons in 1906. The trading profits were £41,730, as compared with £157,127 in 1907. After paying for administration expenses and exploratory work, and settling the smelter smoke suit, an available balance of profit remains of £28,112. Exploration work has been chiefly confined to diamond-drilling. Here and there ore fairly high in copper has been found.

ROSSLAND, BRITISH COLUMBIA.

Output.—Consolidated M. & M. Co.—Canadian Metal Company.

The output of ore from Rossland is now nearly 5000 tons per week, despite the fact that the Le Roi is shut down. The Centre Star group alone is shipping 4300 tons. The rich ore-shoot in the War Eagle mine is developing splendidly. It is about 400 ft. long and 50 ft. wide, and has been cut on both the ninth and tenth levels of the mine. Several thousand tons of ore have been taken from this vein, and it is estimated that a million dollars worth of ore can be mined. The average tonnage for April from the lode carried \$30 per ton in gold. Good results are being obtained in all of the Consolidated company's claims, including the Idaho and Iron Mask. The net earnings of the Rossland property of the Consolidated company will run from \$30,000 to \$40,000 per month. In the long-neglected South Belt recent finds seem to bear out the statement of Clarence King that the best and richest mines in Rossland would be in the South Belt. The rich showing made by the Blue Bird, the ruby silver lately found on the Hattie Brown, and other finds have turned interest in this direction. New York capitalists will do a lot of work there this summer. The three mines now working on rich galena are the Blue Bird, Hattie Brown, and Richmond. At a point 30 ft. from the surface average samples taken from a 2 ft. lead in the Blue Bird gave the following returns: gold 9 oz., silver 139 oz., lead 12 per cent.

The Centre Star War Eagle group of mines, controlled by the Consolidated Mining & Smelting Co. of Canada, is in a position to mine and ship for treatment to its smelter at Trail about 10,000 tons of ore per week, should prices warrant, which is more than double the present output. The Granby Con. Mining, Smelting & Power Co. in the Boundary, by the middle of July expects to have the entire battery of eight furnaces at the Grand Forks smelter renovated and enlarged. This will give a smelting capacity of 4500 tons

per day, which the mines at Phoenix can supply without trouble. While the Le Roi mine is closed down, the managing director, A. J. McMillan, is in London, and the mine superintendent, A. G. Larson, is visiting the large mining and smelting plants of Colorado, Utah, and Montana. There is little doubt that the Le Roi will be working on its plan of deep and extensive development in the next few months, and if the price of copper and silver should rise, ore now ready for stopping in the mine could be shipped profitably. The British Columbia Copper Co. could also augment its output, and no doubt will in the next few months, as by that time the spur track will have been completed to its newly acquired mines in Wellington camp, where a big tonnage is awaiting shipment. The Dominion Copper Co.'s property is shut down, and the affairs of the concern are in a regrettable mix-up, but an order to resume work at the mines would come in a short time if it was known that a profit could be realized. The Le Roi No. 2, Ltd., at Rossland, is shipping about 700 tons of ore, or a little under that, per week, this ore being of a higher average grade than the usual Rossland ore, and assaying about \$23 per ton. While the output of the Le Roi No. 2, Ltd., could be increased, they are not in as good a position as some of the larger companies, and besides this, the company is now re-timbering the main Josie shaft, with a view to centering its energies on the deepening of that shaft from the 900-ft. to the 1200-ft. levels and opening up the ground between these levels. The smelter receipts at the Le Roi No. 2, Ltd., for March were \$62,361. Of this amount \$59,151 was in payment for 3263 tons of ore and \$3210 was in settlement of 112 tons of concentrate; a price of \$18.11 per ton for the ore and \$29.55 per ton for the concentrate, after deducting freight and treatment charges. This concern expects to pay regular quarterly dividends of two shillings per share this year, having just paid one such dividend. The company uses air power wherever possible about the mine. It is obtained from the Consolidated company. Electricity is used for hoisting, being taken from the high-voltage lines of the West Kootenay Power & Light Co. Its ore is smelted at Trail at a little over \$5 per ton, including freight.

At Nelson, the Silver King is once again on the shipping list, sending over 500 tons of ore per week to the Trail smelter, and with prospects of larger shipments later on. Arrangements are in progress for the resumption of work at the La Plata and at the mines and smelter of the Sullivan Group Mining Co., but the future of these two properties will hinge on the price of silver and lead and some further light on the zinc question, both from an economical and treatment standpoint, this applying in particular to the latter property. In addition to the difficulties confronting the Sullivan company in regard to the mine, its financial affairs are being adjusted, but it is thought that the near future will see this part of the business in working form.

The Canadian Metal Co., of Nelson, is going into liquidation. It controls some lead-zinc mines, and a couple of years ago built a zinc smelter. Owing to certain concessions and the proximity of a plentiful supply of fuel, this zinc smelter was built at Frank, Alberta. It was a failure, being too remote from the source of ore supply. The company later bought the old smelter at Pilot Bay, on Kootenay lake, and remodeled it, but no great success has followed this enterprise. A new company will be registered as the New Canadian Metal Co., Ltd., with a nominal capital of \$1,100,000, divided into 100,000 shares of a par value of \$10 each, and 100,000 shares of \$1 each. The shares will be issued as 75% fully paid, the amount of 25% of the par value remaining due from subscribers to the new shares. There is a good field here for a zinc-smelting works, and it is to be hoped that the New Canadian Metal Co. will make more progress than the old one did; if so, the results will be mutually beneficial to the company and to the much perplexed zinc miners, who are feeling chum again, now that it is known that the Payne Act imposes a duty of one cent per pound on zinc in ore entering the United States. Up to this time a quantity of the British Columbia zinc ore had found a market in the United States.

DENVER, COLORADO.

San Juan Conditions.—Clear Creek District. —Asbestos Industry in Wyoming.—Opening the Bijou Coalfield.—Cripple Creek.

The unusually late spring has delayed the opening of many properties in the San Juan district. The Silverton Northern railroad has finally been dug out of the snow, and is handling an enormous traffic made up of the winter stock of ore in out-going shipments and of supplies and new machinery being sent in to the mines on Red Mountain. The Ross Mining Co. has closed the bidding on the contract to extend the Pittsburg tunnel under the Champion mine on Sultan Mountain. The Mountain Flower Co. has started extensive development work on its claims in the upper San Miguel district. A telephone line is being built to the mine and concentrating machinery is being assembled for the new mill, which is nearly completed.

The operators in the Clear Creek district are much encouraged by the new smelter that is being built at Utah Junction, north of Denver. There is scant prospect for the success of the venture, however. On May 7, the fiftieth anniversary of the discovery of gold in the Rocky Mountains was celebrated at Idaho Springs. A boulder, suitably engraved, was set on a concrete pedestal, on the spot where the first nugget was discovered. A company has been organized at Empire to develop the Headlight group of claims on Lincoln Mountain. Surface improvements have been made and shaft-sinking begun. The Santiago mine, of East Argentine, has ceased operating on the leasing system, and will henceforth be operated on company account. The Argentine Central railroad has been completed almost to the mine, and the company believes that it can maintain a steady output.

A new industry is just starting at Caspar, Wyoming. The American Asbestos company is developing the extensive deposits of asbestos situated near there. Mining machinery and a fiberizing plant are being installed. The company expects to be competing with the Canadian product in the early fall.

The benefit of the Geological Survey work on the Denver coalfield is already becoming evident in the extension of the field to the vicinity of Fort Morgan. The Bijou mine has been opened to supply the local demand, and a large plant will be installed during the summer.

The Cripple Creek Deep Drainage tunnel is now more

Cripple Creek Tunnels.

than half completed. The progress during April was 986 ft. at the three headings. This is a phenomenal record for driving in the Pikes Peak granite. The management of the enterprise is worried over the problem of raising the remaining \$166,000 necessary to complete the work. The annual meeting of the Eagle Ore Co. was held on April 17, and the old officers re-elected. The company sampled 193,000 tons of ore, valued at over \$5,000,000, in 1908. The El Paso Consolidated Gold Mining Co. has let 31 leases on its Beacon Hill estate. This mine will be the first benefited by the drainage tunnel, and vigorous preparations are being made to take advantage of that event. The Golden Cycle Mining & Milling Co., owning and operating the Golden Cycle mine at Cripple Creek, and the mill by the same name at Colorado City, has purchased the holdings of the Pike's Peak Fuel Co., of Colorado Springs. A power plant is to be erected at the mine, to supply power to the mill and to customers in the city.

CANANEA, MEXICO.**Output of Copper.—New Plant.—Tailing Dam.—Mine Development.**

The copper output for the Greene Cananea Co. for the month of March was 3,950,000 lb. The charge sent to the blast-furnaces, exclusive of coke, was 54,600 tons. The reverberatory smelted 7400 tons, mainly flue-dust, with 800 tons of calcine. The milling plant treated about 57,000 tons of ore, producing 18,000 tons of concentrate, dry weight, showing a reduction of a little better than 3 tons to 1. The output of the mines was approximately 80,000 tons, of which 20,000 tons was first-class ore sent direct to the spreading beds, and 60,000 tons second-class to the concentrator. The new large compressor is being installed at the main power-house, and the pipe-line to the various mines is being laid. This line will be 10 in. to the Veta No. 5 shaft, from where it branches to the America and Duluth 8 in., and from the Veta to the Oversight and Capote 8 inches.

The new dam across the gulch immediately below the concentrator is completed. This dam is for the purpose of catching the tailing, which carries 1% or more of copper. Although as yet no way has been found to treat this tailing profitably, L. D. Ricketts believes that the time will come within the next few years when they can be handled advantageously. At the new dam there is being installed a three-plunger electric pump to send the clarified water back to the concentrator. Much of the concentrator-water is flumed down from Puertocitos canyon. This new pump is needed to help out the supply, particularly during the dry season. The only recent improvement of importance at the smelter is the use of the new matte-pits, where matte from the reverberatory furnace is dumped and later sent to the blast-furnaces. Handling the reverberatory matte in this manner has reduced the coke-consumption at the furnaces considerably.

At the mines, development work is being pushed. In a cross-cut of the Henrietta No. 3 tunnel a 15-ft. vein of 10% ore has been found. Two prospect tunnels are being driven in the Pavo Real workings, showing only bunches of ore so far. At the Kirk another shaft has been put in operation. Work is begun at an old shaft between the Kirk and the America mines. This is one of the old America workings. Probably the most puzzling problem in the development of the mines is to find ore on the 200-ft. level of the America. On the 100-ft. level are good stopes of both first and second-class ore, the car samples of the first-class running 7 to 10% copper, but in spite of rather extensive development, comparatively little ore of value has been discovered below this level. At the Elisa a new 250-ton bin, with a conveyor and picking-belt system, similar to that at the Duluth, has recently been completed. L. D. Ricketts and W. D. Thornton have been for a month on a hunting and business trip in Mexico. Mr. Thornton, who is president of the Cananea Consolidated Copper Co., is also a director of the International Smelting & Refining Co., and it is supposed that the business was in connection with the latter company.

NEW YORK.**Electric Companies Amalgamation.—Fink Smelter.—Greene Liquidation.—Lead Prices.—Curb Stocks.**

The Westinghouse Electric and the General Electric and their subsidiary companies are to be brought under one management. It is probable that they will be connected with the Amalgamated Copper Co. Representatives of the Amalgamated Copper Co. and of the International Smelting Co. have been instructed to take options on desirable coal and iron lands in the southwestern and western States. Options have been taken already on extensive coal lands in New Mexico and southern Utah. Samuel Newhouse states that plans are being drawn for smelters in Utah and Nevada, where the Fink process will be employed on a large scale. The experiments at the Boston Con. smelter have shown that the process can treat, at a cost of about \$1.50 per ton, the ore now being shipped to and smelted by the A. S. & R. Co. at a cost of \$6 per ton. The receiver of the Greene Gold

Silver Co. will sell the company's holdings by auction in New York on July 1 next, and will apply the proceeds to the payment of the company's debts. W. C. Greene, the promoter of the company, claims that it owes him \$2,000,000, but this amuses the stockholders, and does not trouble the receiver. Greene is still in Mexico for "the good of his health," and is not likely to visit New York and press his claims. It is probable that the sum realized by the sale will be insufficient to liquidate the company's debts.

Notwithstanding the fact that zinc ore abounds in many districts in Mexico, up to the present time no substantial attempt has been made to smelt zinc in Mexico on a commercial scale. Recently J. O. Willett, of Saltillo, Mexico, received a Government concession for zinc smelting. A syndicate is being formed by American capitalists, and it is probable that a smelter will shortly be erected at Sabinas. The price of lead has advanced several points. Reports from London are that J. P. Morgan has succeeded in perfecting arrangements whereby large international dealers in lead in Europe will work in unison with American dealers, and that the price of lead will be advanced, with that of copper, to high figures. To allay the fears of metal workers, Edward Brush, vice-president of the A. S. & R. Co., has issued the following official notice: "The American Smelting & Refining Company knows of no world-wide lead trust that has been formed to advance prices being in existence, or in process of formation. The A. S. & R. Co. has not joined any such trust, and does not expect to do so. The lead market is strong at the present time because of the great Australian lead mines being closed down by strike. The quotations of lead are now abnormally low, and the price will advance somewhat, due to natural causes. The A. S. & R. Co. does not look to see any abnormal advance in the price of lead, and knows of no reason which is likely to bring about any abnormal increase in price."

Mining stocks on the New York curb market continue heavy. Strenuous attempts have been made to infuse life into cobalt-silver stocks, but brokers report unsatisfactory results. Dull times on the curb have caused a number of the brokers to fail.

WASHINGTON.**Lead Tariff.—Customs Court.—Homestead Laws.**

The Senate has agreed to a duty of 1½c. per pound on the lead content of all lead-bearing ores, thus settling this feature of the tariff bill.

A bill to create a United States Court of Customs Appeals has been introduced in the House by James C. Needham, Representative from Modesto, Cal. The measure provides for a chief justice and two associate justices, at a salary of \$10,000 each, and that the Court shall meet in Seattle, Portland, and San Francisco. Mr. Needham presented another bill which provides for a continuation of the investigation of the rivers and water resources of the United States by the United States Geological Survey. Simon Guggenheim, Senator from Colorado, has introduced a bill appropriating 25% of all money received for mineral land within the State of Colorado for the maintenance of the School of Mines established at Golden. Thomas P. Gore, of Lawton, Oklahoma, the blind senator, has introduced, by request, a bill granting additional rights to homestead settlers on public lands. It provides that any homesteader shall be allowed to leave from October 15 to April 15 of each year for the purpose of securing employment when such cannot be obtained on the homestead. The bill contains the provision that no leave of absence after the first shall be granted unless the homesteader makes affidavit to the effect that he saved at least \$10 per month for improving his homestead while he was away, and that he has expended in the way of clearing the land and bringing it under cultivation since his last absence the sum of \$20, times the number of months of his last absence, his own labor to count for reasonable wages. A bill authorizing reinstatement of commutation certificate for homestead entries when cancelled for lack of residence if entryman has resided continuously on entry the eight months preceding the making of proof, has been presented to the House by Moses P. Kinkaid, of O'Neill, Nebraska.

TORONTO, CANADA.

**Gillies Limit.—Gowganda —La Rose.—Nipissing. —Silver Queen.—
Temiskaming.—Cobalt Shipments.**

The Ontario Government is offering for sale 1000 acres of the Gillies Limit adjoining the Cobalt mining district. The Provincial mine is situated in this area, but is not to be sold. The property will be disposed of in lots of 20 acres each, subject to 10% royalty on the value of the output and a proviso that successful tenderers must expend \$400 annually in development for 7 years. Tenders will be received up to June 1. Mining men are disposed to consider the action of the Government as ill-advised at the present time when investors are surfeited with mining propositions of a much more tempting character. Notwithstanding the experimental work undertaken by the Government the Gillies Limit is still an unknown quantity as regards valuable mineral discoveries. The Provincial mine did indeed make one or two shipments last year, but has made none since, and from the care that has been taken to suppress all information as to the value of the ore obtained, or the extent and character of subsequent development the inferences drawn are naturally unfavorable.

The isolation of Gowganda is so complete that the Post Office Department has announced that no mails, with the exception of letters, can be forwarded to Gowganda, Elk Lake, and Wigwam until navigation opens, which at earliest will be about the middle of May. A Government engineer has been sent to survey a wagon-road which is to be built from Charlton at a cost of \$50,000. Construction will not commence until June. During the last week or two, while the winter roads were still passable, freighters were charging \$100 for the round trip of 42 miles from Charlton to Elk Lake. A steam-boiler which was shipped from Charlton to Elk Lake for the Silver Horn mine west of the latter point was three weeks in traveling 21 miles, and the cost of transport was \$2000. It is evident that not many dividends need be expected so long as such conditions obtain.

The La Rose, at Cobalt, has secured the Lawson property by exchange of stock for outstanding shares of the Lawson Mines Ltd. to the extent, it is stated, of about \$1,750,000. The property acquired embraces 40 acres cornering on the Crown Reserve and lying adjacent to the Kerr Lake. Development has been retarded by protracted litigation. The Silver Leaf shaft, which was sunk by the Silver Leaf Co. on the Lawson tract, owing to a mistake in the survey, has been pumped out and driving will begin at 160 ft. Another shallower shaft will be put down to the same level. The annual report of the Nipissing was of a highly optimistic character, showing the total value of ore produced in 1908 to be \$1,410,068, and the net profit \$903,090. The net surplus on hand at the close of the year was \$803,326. President Earle stated that of the 846 acres owned by the company 383 are still unexplored and the remaining 463 only partly prospected and developed. The vein of rich ore at the 172-ft. level in shaft No. 64 is 16 in. wide and assays about 1700 oz. silver per ton. It is estimated that every block of ore on this vein 100 ft. long and 100 ft. deep, of this average grade, will net \$1,750,000. The Argentum Mines Ltd. has entered into an agreement under which it will operate the Foster in connection with its own mine for five years. The annual meeting of the Silver Queen shareholders was held here on April 28, and the financial statement was by no means of a hopeful character, the principal available asset being the low grade ore on the dump, the value of which is estimated at \$25,000. The Northern Custom concentrator will begin treating this early in May. Prospecting by diamond-drill will be carried on in the hope of again striking good ore. Capt. W. H. Jeffrey has resigned his position as engineer of the Chambers Ferland, and on May 1 C. Watson, assistant superintendent of the Nipissing, was to replace him. A new vein carrying cobalt and native silver, 2 to 3 in. wide, was recently uncovered in trenching. At the Temiskaming rich ore is being taken out of the vein on the Gans area at the 200-ft. level, which is 10 in. wide, with good milling ore on either side. A steel shaft-house,

open on all sides, the first of the kind in Cobalt, is being erected. It is over 70 ft. high and rests on a solid cement foundation. The new 3-compartment shaft is down 350 ft. and when complete will be connected with the workings from the other shafts by cross-cuttings. The Kerr Lake has the deepest workings of any in the camp, being down 400 ft. The manager, S. R. Heakes, states that they have ore at that level averaging as high as any. The output, however, is being steadily restricted to 180,000 oz. silver per month, or about two tons of ore per day. The total cost of production is 7c. per ounce. The assets of the Green-Meehan, in accordance with a vote of the shareholders, have been made over to the Consolidated Silver Cobalt Mines Ltd. Trethewey has declared an interim dividend of 10%, payable May 15. The main shaft of the Hargrave is now down 215 ft. When it is 92 ft. deeper a level will be run in as far as the Kerr Lake boundary to catch the Kerr Lake vein at that depth, which is supposed to extend into the property. The Coleman Cobalt property, belonging to the Amalgamated, has been secured by the Michigan Development Co., organized by Detroit men with S. D. Madden as manager, and is being operated with air supplied by the Kerr Lake Majestic. The shaft is down 60 ft. The Michigan has also leased the Silver Bird, one of the swindler Frank Law's flotations. Frank C. Armstrong, of New York, this week brought a large party of Nova Scotia and New Brunswick capitalists to Cobalt to inspect the properties of the La Rose and other mines. Shipments continue heavy, the total for the two weeks ending April 24, being 1139 tons. But the number of contributing mines is comparatively small.

JOHANNESBURG, TRANSVAAL.

Randfontein Central Mill.—Stope-Drill Competition.

No mining group advertises itself less than that controlled by Sir J. B. Robinson in the West Rand. Formerly, when the Randfontein group was anything but progressive, this lack of information was unimportant. Today, however, big movements are on foot and reliable data are welcome. The announcement is made with seeming authority that the work of excavation for the erection of the authorized 600-stamp mill has already been commenced at the Randfontein Central. This is to be supplemented by 16 tube-mills, and is to be driven electrically, each ten stamps being run by an independent motor of 40 to 45 hp. as at the Simmer Deep. This will be the largest stamp-mill in the world, and indicates how far the policy of centralization is being carried in Rand practice. Following the popular ideas of today—first put into practice by the Bantjes company—the designers of the new Randfontein mill propose to house the amalgamating tables, together with the shaking tables usually below the tube-mills, in an entirely separate building. The mill itself will come under the engineer's department.

The underground elimination trials of the Stope-Drill Competition have now been commenced and the early results have proved the danger of placing too much reliance in the order of merit established by the surface tests. The Westphalia, which ran wonderfully well on surface, making 4.21 in. per minute on running time, has shown up badly underground. Its automatic feeding device gave trouble and the steel jammed in the hole frequently. The Murphy ran very steadily underground and averaged 1.8 in. per minute. The results of the surface trials have been tabulated by the committee and show that the Siskol heads the list with the remarkable speed of 4.34 in. per minute, with the Westphalia second at 4.21 in. The Siskol is a reciprocating machine, weighing 95½ lb., using hollow steel, while the Westphalia is of the hammer type. The third on the list is the Chersen, which made 4.11 in. per minute. This is of the reciprocating type. Special interest attaches to this machine owing to its local origin and to its comparatively extensive use in the mines, where it has given satisfaction. The two Denver drills, the Murphy and the Waugh, stand eighth and twelfth in the surface trials, with speeds of 2.92 and 2.43 in. per minute respectively.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Size of grain is an important factor in determining the fusing behavior of clays.

Silver purchases during the year 1908 amounted to 33,404,136 troy ounces. Of that quantity 3,012,532 oz. came from parting gold bars.

Anhydrous silica is practically inert at ordinary temperatures, but at temperatures attained in brick kilns it becomes active, expanding and forming many compounds.

Diamantine is a product of the electric furnace, practically a silicide of aluminum, formed by heating silica and alumina together. It is a refractory material of value for coating the interior of furnaces and flues.

Excess alkali in cyanide solutions is not the same as protective alkali. The latter is determinable by direct experiment only, whereas excess alkali is a matter of easy estimation by ordinary alkalimetric methods.

Graphite exists in two forms: crystalline (or flake) and amorphous. It is known to the trade by the names of black lead, plumbago, and graphite. Black lead usually refers to the inferior grades of graphite, plumbago to the Ceylon product, and graphite to the American product.

Lubrication is effected by interposing between the surfaces, films of liquid or soft solid substances, which decrease friction. If the liquid film is too viscous, or if the soft solid substance has too much body—not of the proper consistence—a condition exists which is similar, but in a lesser degree, to that when two solids rub together.

Milk of lime was used for chemical treatment of boiler water as much as 50 years ago by Clark. It is still the best treatment for waters the hardness of which is due almost exclusively to bicarbonates of calcium and magnesium. It has no effect on neutral calcium sulphate, which is a common cause of hardness in natural waters.

Surface tension is due to the fact that particles on the surface of a liquid are not affected by molecular attraction on the outer side. Since material tends to move from points of low to points of high-potential, the surface particles strive to reach the interior of the liquid, and thus produce a tension of the surface.

Holes in castings are generally filled by means of a paste consisting of powdered sulphur 1 part, sal-ammoniac 2, powdered iron turnings 83. This sets but does not repair the weakness caused by the defect. That may actually be done by the use of thermit, if the surface of the cavity is sufficiently accessible to admit of cleansing. A casting, however, containing visible blow-holes will almost certainly con-

tain others, and is liable to be badly piped. Hence it should not be trusted where subjected to much strain.

Mining claims may have broken end-lines, according to decisions of the courts, but the extra-lateral right is not conferred except as it would proceed from straight parallel end-lines. It is doubtful whether the Land Office would issue a patent to a claim when the boundaries by original location were laid down with end-lines containing any angle or change of course in their length.

Magnesium salts are the most corrosive of any that are usually found in boiler waters. Besides their indirect corrosive action, in the case of magnesium sulphate, there is a possibility of forming hard scale through reaction with calcium carbonate. If any magnesium sulphate is present, at high pressures the following reaction may take place:

Mining claims on the Rand are about 15 acres in extent, and ownership is restricted within vertical bounding planes, no extra-lateral rights being conceded. The rule originally prevailing among engineers for determining the proper relation between vein-volume and milling equipment was one claim for each stamp-head in the mill, the stamp-duty being assumed at 5 tons per diem. The increase in duty of stamps, and the variations in gold-content in the veins, have led to providing five claims for each stamp-head in more recent estimates.

Toughness is the most essential quality in paving brick. It is conditioned by the character of the clay and the method of burning. It is necessary that the brick should be brought to the point of incipient fusion and held there long enough to produce a well-bonded homogeneous mass, but without complete fusion. In a good paving brick the unfused particles are cemented by thin films of newly formed silicates. Complete fusion results in the formation of a worthless glass. While it is technically possible to make pavers from a wide variety of clays, it is not economical to do so except with clays having a range of at least 400 degrees between incipient and complete fusion.

Jade is a term loosely applied to various minerals of a translucent white to dark green color. Typical jade is of a lustrous dark green shade, and is either jadeite, a mineral belonging to the pyroxene group, or nephrite, a variety of amphibole. Both are used extensively in China, nephrite being the more common. It is found in the Far East, in New Zealand, Mexico, and Alaska. The white variety of nephrite is tremolite, the dark green, actinolite. Its hardness is that of quartz and its specific gravity from 2.96 to 3.1. Jadeite is heavier, ranging from 3.33 to 3.35. It is the more valuable of the two kinds of mineral commonly known as jade. In composition it closely approaches spodumene, which yields several varieties of gem stones.

payment in full for work done in the month of are added below, with a space for the employee's signature. They are issued to the men a few days before pay day for examination and, if necessary, correction before the pay checks are drawn. On pay day the men bring these receipts already signed to the office and exchange them for pay checks. My experience is that the time saved in paying off more than compensates for the slightly greater clerical work (which can be done at any time), and that this system is especially convenient where duplicate receipts for all payments have to be sent to the head office.

The supply book is arranged as above (Table IV). The capital letters in the "Charge account of" column correspond, of course, to those used in Forms 2 and 3A. The totals of amounts charged to accounts A, B, etc., are entered at bottom of last page for the month. To collect these the right-hand portion of Form 3A, or a like arrangement on loose paper, can be used.

The boarding house supply book is in the same form except that there is no "Charge account of" column. In these supply books the values are figured with the freight added. The amount on hand at end of month is checked by actual inventory at least every quarter. I usually carry the cooks and waiters in the general time book, and a line in the general supply book for the totals of the boarding house supply book, the "Boarding house account" being assigned its capital letter in Forms 3A and 10. The two last mentioned forms are found in books and loose sheets similarly ruled are used if copies are required by the head office.

In conclusion as much as possible of the form filling should be done in the office, and very little of this put on the foreman, whose place is now at the mine. Such work is often so congenial to him and in practice even Form No. 2 is often filled in with some help from the office staff. All forms should have ample space and not be cramped as an apart. This particularly applies to those used by the foreman.

Whether such accounts as M, *Logbook*, *mine*, and P, *Miscellaneous*, shall be distributed at the mine or head office is a matter for arrangement with the directors. I have found the system of forms described above a convenient method of keeping accurate record of the cost of all operations at mine and all other matters which should be recorded except those which are covered by the accountants' books.

EDWARD WESTER

Denver, Colorado, April 19

How It Strikes an American

The Editor

Your contributor, Mr. Edm. D. Carthy, has an interesting article on "How It Strikes an American" on returning home from South Africa, where, on the question of ventilation, it is well known that the Transvaal Government, partly on account of underground workers, had a law passed which required the number of workers and the amount of gas in the mine to be reported to the Government. The number of workers and the amount of gas in the mine must be reported to the Government.

tions and ventilation. For instance, the Cunderella Deep, in its report recently issued, mentions that until November last the maximum allowed was 100. As the company desired to increase the amount of development the directors had to approach the Government, which at once allowed an increase of 100, and providing certain additional ventilation plant was installed, a total of 200 would be allowed. This factor must be taken into account in all plans for mine extension in South Africa.

EDWARD WESTER

London, April 20

While it is true that in America the number of men allowed to work in any one mine is not limited, the same result is indirectly accomplished in all coal mines by the common provision that a certain amount of free air per minute must be furnished for each man and mule in the mine. An ordinary requirement in a non-gaseous mine is 100 cu ft per man and 200 per mule. In mines yielding gas in quantity the requirement is higher. The great extent of underground workings in the Rand mine has introduced problems of ventilation similar in some respects to those of the non-gaseous coal mines. This is a stage in metal mining not reached in America, except in special instances, such as certain mines at Cripple Creek where gas is given off in quantity. So far the number of such instances has been so small as not to require special regulation. Further

Mine Surveying Hints

The Editor

As I read with interest Edm. D. Carthy's article on "Mine Surveying Hints" in our issue of February 14, and can see considerable advantage in inclined haws as the telescope and box instruments have them, I have had considerable experience in underground surveying and to transfer surface line underground by means of two plane tables, which also serve to maintain a slight ventilation, make it desirable to line up with them by the ordinary method of sighting first upon one then upon the other. The best method I have discovered is to find the centre of gravitation of each and then line up with these two points. This can be done as follows:

Place back of each wire against a corner as close to the wire as possible without touching it. Then place a third wire on top of the middle of the other two.

of one of the wires... the other two... the middle of the other two... the middle of the other two...

shadow of the opposite wire as B to fall on the board back of it. Now follow this shadow as it moves on the top of the board, due to the oscillation of the B wire, until it reaches the end of its course and starts back, and place a pin in the board at this point, as at C. Now follow the shadow back until it reaches its limit in the opposite direction, and place another pin at the point, as at D. Place a pin mid-distant between these two pins, as at E, and the centre for the B wire is found.

Take the light from behind the A wire and place in the same manner behind the B wire, and proceed to follow the shadow of the A wire on the board back of it.

Bisect the distance between the pins as found, and place a pin at the point for the centre of the A wire. Line up with these two centre pins. Being stationary this is easily and quickly done. I submit this in the hope that it may prove a help in what is ordinarily a tedious operation.

H. H. HOLBERT.

Courtland, Arizona, March 7.

Vacuum-Pump in Cyaniding.

The Editor:

Sir—With reference to the article on 'The Vacuum-Pump in the Cyaniding of Sand', reproduced in your issue of February 27, Mr. Caldecott is in error in stating that "the use of the vacuum-pump in cyanidation is as old as the first introduction of the cyanide process in this district by J. S. MacArthur in 1890." The vacuum-pump and the cyanide process were both introduced into South Africa before J. S. MacArthur ever arrived in that territory. It is true that there has been a tendency in later years in South Africa to regard the use of the vacuum-pump as of no advantage, but the continuous use of this appliance elsewhere has amply justified our original recommendation of it in connection with cyanide treatment.

ALFRED JAMES.

London, April 5.

A Case of Salting.

The Editor:

Sir—Some years ago an engineer was called upon to investigate cyanide operations in a plant connected with a property of which I later had the management. The primary cause of the investigation was a very strange shortage of bullion recovered when checked against estimates based on assays. After a general survey of the plant, standardizing solutions, etc., a number of assays were run on original sand and slime, and on residue of the same after treatment. The cyanide solutions before and after contact, and after passing through the zinc-boxes, were also tested. The results showed such wide disparity that it was resolved to assay all the fluxes. These were found to carry gold and silver, and a fresh lot was ordered. The latter, arriving sealed, were accepted as free from precious metals, but on running the usual blanks a variable gold-silver button was still found. Finally the unused cupels were

ground and assayed. All the bone-ash was found to carry gold and silver. We concluded that this salting was accidental, and arose through carelessness in drying precipitate. The dust therefrom settled in receptacles that contained flux, or other material, and being in the bone-ash when the lead buttons began to melt, caused a continuous picking up of the metal in the bath from the surface of the cupels.

H. VINCENT WALLACE.

Nogales, April 15.

Fighting Fire With Snowballs.

The Editor:

Sir—While on a visit recently in the Sierras, at the Morning Star mine in Plumas county, California, we were startled at breakfast by the cry of 'fire'. We ran to the rescue, and found flames leaping up the hoist-tower. Something had to be done quickly or the fire would be beyond control. No ladder or other means could be found for reaching the fire; not even a bucket. This was reprehensible, to say the least; but how many other properties have neglected fire-precautions? Someone thought of snowballs, and immediately the big wet snowballs were flying from a dozen hands, at and above the flames, which by that time were mounting high up the structure. The snow stuck to the boards, melted, ran down, and smothered the fire in a very short time. Thousands of dollars worth of property and much valuable time were saved, and the men continue to hold their jobs, all because a trick we had learned as boys was put to a useful end.

W. L. COBB.

San Francisco, April 21.

Surface retardation in open channels, or, in other words, the phenomenon that the filament of maximum velocity in a stream is some distance below the surface, is explained by a simple hypothesis advanced by A. H. Gibson in a paper read before the Royal Society, January 14, 1909, on the 'Depression of the Filament of Maximum Velocity in a Stream Flowing Through an Open Channel'. The frictional retardation due to sides and bottom tends to set up eddying movements in the water, the plane of the eddies being inclined inward toward the surface of the water. The tendency toward this eddying flow, combined with the free flow along the stream, produces a surface-current setting from the sides toward the centre of the stream, and correspondingly an outward bottom-current. These currents carry the slower-moving water which was in contact with bottom and sides and was retarded by their friction, toward the surface at midstream, and retard the velocity of the downstream flow at that point. Near the middle the currents set downward, receiving accelerated downstream velocity, and finally flow outward again near the bottom. Their retarding effect makes the velocity near the surface less than the ideal velocity of flow, whereas at some depth below the surface they have a lesser retarding effect. Mr. Gibson has demonstrated the existence of the cross-currents by observations in a test-flume, in a river channel and in a narrow earth canal.

CALABACILLAS GOLD MINE.

Written for the MINING AND SCIENTIFIC PRESS
By CHARLES WALTER GEDDES.

The Calabacillas mine, in the State of Chihuahua, Mexico, close to the junction of the States of Chihuahua, Sinaloa, and Durango, is perhaps one of the most interesting mines of the entire West Coast, not alone for the reason of its being one of the few new gold mines of Mexico, but also because of its development, since its discovery by a native Indian, by local Mexican owners. It now represents one of the few 'one man' gold mines of the world. The purity of the gold contained in the ores, and the almost perfect saving by direct amalgamation, allows the use of the oft abused term 'free-milling ore.'

The original discovery was made accidentally by an Indian, bearing the same name as the famous Apache chief, Geronimo, in the year 1899. He sold his entire interest for an old musket and two cows.

Calabacillas Mill.

The property then passed into the hands of a Mexican syndicate and was worked for several years on a unique co-operative plan. Starting on the surface where rich ore was discovered, shallow shafts, pits, and trenches were made and the ore so extracted divided among the different owners in proportion to their holdings in the syndicate. After this division, by weight or measurement in boxes, with no regard to the values contained, the respective owners would convey the ore to their homes, or haciendas, and treat it in arrastres.

Later two Bryan mills were installed, and the operations better organized. During this period the property produced \$530,000 gold at small expense. The usual vicissitudes attending the transition of a prospect into a mine occurred during the next two years until the entire property and plant was purchased outright and individually by W. H. Brevoort, of New York and Paris. The mine is now in active operation, and has made a total production to date of \$900,000. The mine is in the same range of mountains, paralleling the west coast of Mexico, in which are the famous old mines of Guadalupe y Calvo,

Morelos, Batopilas, Son José de Gracia, and the more recent Lluvia de Oro, the latter being one of the sensational discoveries of the latter decade. The range is composed mainly of andesite, broken here and there by intrusions and extrusions of later porphyries. At Calabacillas is an intrusion of rhyolite, in andesite, having an average width of about 500 ft. on the surface and traceable several miles, until it is lost under more recent flows, tuffs, and breccias. The intrusion forms a sharp anticline on its contact with the andesite, one leg of the anticline having a dip to the east and the other to the west. Development has so far been confined to the east contact, exposing a zone of brecciated and fissured material extending into the rhyolite a distance of 150 ft. The mass consists of ore-shoots characterized by a regular system of fissuring both parallel and transverse to the main contact. There have been developed four, and possibly five, separate, distinct ore-shoots, varying from 65 ft. by 15, to 100 by 70, and the conditions warrant the expectation of other ore-shoots along the strike.

The brecciated rhyolite has become silicified by percolating solutions, and the gold has been deposited in the fissures and seams of the brecciated mass, in connection with different iron minerals. The term 'free-milling ore' has been so misused that it has lost practical significance, but at Calabacillas is an absolutely typical free-milling ore. Fine-grinding tests indicate that with sufficient plate-area from 95 to 97% of the total gold-content can be saved by amalgamation. The silver content is practically nil, the retorted bullion showing only 35 oz. silver to 500 of gold. Due to the character of the ore the milling practice is simple. The original

mill consisted of two Bryan mills with plate-area of 4 by 12 ft. Later 10 stamps of 850-lb. weight were added. Inside amalgamation was used, with an outside plate-area of 4 by 10 ft. to each battery. A small cyanide plant was installed, having a daily capacity of 15 tons. Recently another battery of 10 stamps, of 800-lb. weight each, was installed, and the Bryan mills discarded. There is now being installed a very simple cyanide leaching plant, equal to the present capacity of the 20 stamps, which is 40 to 50 tons per day.

The ore as broken in the mine is delivered to the mill by a surface tramway, passed over grizzlies, and the coarse through a 10 by 11-in. Dodge crusher, crushing to one inch; then to the batteries. The stamps have an 8-in. drop, 100 drops to the minute, and crush the ore through No. 30 mesh screens, using inside as well as outside amalgamation. The pulp is carried direct from the plates, by launder, to the tailing dump, where 15 tons daily are used in the present cyanide plant, the remainder being impounded for future treatment.

The average daily run shows a saving of 80% by

straight amalgamation, when crushing through 30-mesh, while the cyanide plant, after 5 days leaching, recovers 80% of the value contained in the tailing, making the total saving 96%. Below are monthly records taken at random from the mill books, showing recovery by amalgamation alone, and *not* including results of the cyanide plant:

Tons milled	820
Assays: Heads	\$15.00
Tailing	2.89
Extraction	12.11
Extraction, %	80.70
Amalgam recovered, oz.....	2123
Bullion retorted, oz.	783
Mercury recovered, oz.....	1326
Melted bar, oz.	571
Assay of bullion, gold-fineness.....	840
Silver-fineness	63
Total value	\$9933.38

The low tonnage is due to scarcity of water, but recently, in opening a new level, it appears that this difficulty has been overcome.

Considering that this ore, coming as it does from a depth of 400 ft., is crushed through 30-mesh only, it would seem that the above recovery by amalgamation is remarkable. Steam is the power now in use, but plans are being made for the installation of electric power from the Juan de Haro river, distant about two miles from the mine, where surveys and water measurements show 200 hp. available at low water.

SELF-HARDENING STEELS.

*In high-speed steel practice, the disposition on the part of users as well as makers, has been to use one steel for all purposes, tools for cutting hard as well as soft materials (wood among the rest), forming dies, crushers or hammers, rock-drills, and all the rest of the category of tools. Most manufacturers make extravagant claims for universal high efficiency on behalf of their particular steels. It is true that some steels on the market come pretty near fulfilling the various conditions requisite to universal service, not only making good cutting-tools for hard and soft metal and wood, but being suitable also for forming dies, crushing-tools, hammer-tools, and the like. For the most part, however, the high-speed steels now on the market are adapted to particular rather than to general service. Thus a steel highly efficient in cutting hard material often is not so on soft; and one well suited to cutting is not very likely to be well suited to forming dies. One steel said to be superior to any other in all kinds of metal cutting has the composition:

	%	%
Vanadium	0.32	0.29
Tungsten	17.81	18.19
Chromium	5.95	5.47
Manganese	0.07	0.11
Carbon	0.682	0.674
Silicon	0.049	0.043
Sulphur
Phosphorus
Iron	75.119	75.22

Though nothing is said as to its efficiency in tools other than those for metal cutting, the composition of this steel indicates that it is also good for all

tools requiring toughness and wearing quality; so that it may fairly be classed as an all-round steel. Other things equal, it would be highly desirable to have in a shop one all-round steel equally and in a high degree efficient in all sorts of work. The need for so many varieties of tool-steel heretofore has been a source of great inconvenience, of frequent mistakes, and untold annoyance, all which would be dissipated could a single steel be economically substituted for the many varieties now in use. Steels have recently been put upon the market, at prices greatly below those asked for the ordinary grades of high-speed steel, which are especially adapted to some particular class of work, as wood-cutting, for example. These steels are stated to be intermediate between the high-speed and ordinary steels, and evidently are developed from the ordinary self-hardening steels by varying the alloy-content so as to secure the highest degree of toughness and edge-holding quality, essential to tools not expected to stand up to the kind of work required of high-speed tools, rather than red-hardness, which is not essential to this class of tools. They purport to fill a gap which has been recognized ever since high-speed tools first came into general use, furnishing a tool possibly slightly less lasting in service, but at a considerably lower cost. The precise field for these steels remains to be determined. Doubtless they will come largely into use for wood-working and such metal-working tools as require keen edges, but work in such a way (perhaps at slow speed) that they do not get hot enough at the cutting edge to need a high degree of red-hardness. Some of them are stated to be especially adapted to use in forming and blanking dies, drop dies, and like tools, which require great wear-resistance, but which also generate no great amount of heat while at work. The minute structure of high-speed steel, as seen in a fracture, does not differ greatly from that of carbon steel. It is, in general, seen to be of a fine and uniformly granular appearance, with the granules smaller and more uniform, generally, than those of carbon steel. In annealed and forged high-speed steel the smoothness of structure is increased: and when hardened, the crystalline structure stands out clearly though the individual crystals are very minute. Under the microscope the structure is seen to be essentially that of carbon steel with certain modifications or additions. Pearlite is found, though generally in smaller proportion than in carbon steel, and martensite (or hardenite) forms a considerable proportion in many cases. This is true, as might be expected, especially of those steels which are high or moderately high in carbon, and which therefore are quite hard. Austenite is nearly always present in high-speed steel which has been heated beyond the higher critical point, and of course indicates that the steel is tough in proportion to the amount present. Changes in appearance and in structure due to hardening, tempering, and forging, are as noticeable in high-speed steels as in carbon steels.

Each nominal horse-power of boilers requires about 1 cu. ft. of water per hour.

*Abstracted from *Engineering Magazine*.

CYANIDATION OF SILVER ORES.

Written for the MINING AND SCIENTIFIC PRESS
By D. MOSHER.

The object of this paper is to direct the attention of cyanide operators to possibilities still lying dormant in this field and to the necessity for methods that will give a greater range in the treatment of low-grade silver ores by cyanidation. The situation at present as shown by Caldecott,* Hoffman, Hobson, and other specialists is, that although progress has been made in the cyaniding of silver ores, the results on the whole show that not only is the extraction generally poor, but that the cyanide consumption is usually heavy, while the time is so unduly prolonged as to enormously restrict the capacity of plant, thereby increasing the cost of treatment. It is true that 'sliming' methods have improved results, but the remedy in my opinion will be found in the chemical, rather than on the mechanical, side of the problem.

The causes that tend to impede the efforts of the cyanide operator in the extraction of silver from its ores are, the silver present in a metallic condition, the silver sulphide, and the refractory antimonial group of silver minerals, such as pyrargyrite, stephanite, proustite, and polybasite. The insolubility and inertness of these silver minerals to ordinary oxidizing agents is well known; the fouling of the cyanide solution by the formation of soluble sulphides is generally understood, as well as the bad effect on the extraction of the gold and silver in the ore. The haloid silver minerals, such as bromyrite, cerargyrite, iodorite, and embolite, give the highest extraction according to the following equation:

Primary reaction:

Secondary and final reaction:

It is seen that the haloid silver minerals form ideal compounds for successful cyanidation, while the raw sulphide minerals are less docile. The chemical reactions involved in cyaniding the latter are complex, interfering with the solution of the silver, and therefore resulting in poor extractions. The time required to effect solution is unprofitably prolonged, because the reactions, as already stated, are diametrically opposed to each other. The formation of soluble sulphides (K_2S , KHS) as well as the double sulphide salts of antimony ($\text{SbS}_3 \cdot \text{K}_3$), and ($\text{SbS}_4 \cdot \text{K}_3 + \text{H}_2\text{O}$) Schlippe's salt, which also are very soluble, prove extremely detrimental in the cyanidation of silver ores. The indirect formation of sulpho-cyanide may also be noted, and it affects the extraction unfavorably. To some extent these difficulties are overcome by the use of lead acetate.

Cyanide compounds are of delicate chemical structure, are easily broken up by oxidizing agents, and are rendered useless as solvents for the precious metals. The one exception is ferri-cyanide ($\text{K}_3\text{Fe}(\text{CN})_6$). This salt, however, is not very effective.

Cyanide combinations of the heavy metals as Hg (univalent) and Cu (both univalent and bivalent) react with silver sulphide in accordance with the following equations:

The mercuric sulphide, it is claimed, remains insoluble and inert in the tailing.

Copper.—With copper the reaction is similar to the above, but is greatly enhanced by the addition of ammonia to the copper-potassium cyanide solution. The enormous increase in solvent-efficiency for silver after adding ammonia to the cupro-cyanide solution, is in a measure due to the powerful affinity of the copper-ammonia solutions for oxygen, which in practice is introduced by air-agitation. Another point of value is the stability of these copper cyanides in ammonia. They also react readily with the silver sulphide to form silver cyanide and sulphides of copper, that in ammonia oxidize with the greatest rapidity and are thus re-generated. The addition of lime, $\text{Ca}(\text{HO})_2$, to the solution will continually withdraw the products of oxidation in the form of gypsum. The copper-ammonia solution containing a sufficient number of pounds of cyanide per ton acts powerfully on the base sulphide silver minerals, and will dissolve the silver from the ore to a greater extent and with less loss of cyanide than would be possible by the use of plain cyanide methods. Due to the immediate oxidizing action, purification of the solvent and the re-generation referred to, is quickly effected. In my new ammonia-cyanide process, calcium cyanide is to replace ordinary cyanide with the object of reducing the cost to one-fifth of what it is at present.

In the efforts made in past years to effect a greater saving of silver, various oxidizing chemicals have been added to the cyanide. The remainder were not employed either for commercial reasons or for lack of technical insight. They are: Potassium ferri-cyanide, potassium or sodium bichromate, sodium dioxide, barium dioxide, bromo-cyanogen, potassium permanganate, chloride of lime (hypochlorite), hydrogen peroxide, potassium cyanate (KCNO), hydrated manganese dioxide, ammonium persulphates, potassium percarbonates, chlorine, oxygen, chlorine peroxide.

In the treatment of argentite ores these oxidizing chemicals may be highly effective if used judiciously. Most promising of the above group are the peroxides. Sodium as well as barium dioxide can now be obtained at low cost; sodium dioxide with 20.5% available oxygen is now worth about 40c. per lb., and if the demand becomes greater can be produced for less than 15c. Barium dioxide with 8% available oxygen is worth 8c. per lb. These reagents are to be applied to slimes of clean silicious ores as follows: to a 5% sulphuric acid solution, cooled to the freezing point, add the sodium dioxide in small quantities at a time, avoiding effervescence, as this causes decomposition of the peroxide. The almost neutral hydrogen peroxide produced is to be added to the cyanide, the amount of the addition to be gauged by the quantity of sulphur which will inter-

*MINING AND SCIENTIFIC PRESS, March 28, May 2, and Aug. 29, '08.

act with the cyanide and be oxidized to sulphate. By using correct ratios of cyanide and peroxide an equilibrium will be established where no decomposition of the cyanide will occur, and at which point no sulphides will tend to foul the cyanide solution. With barium peroxide a similar method of producing hydrogen peroxide is in vogue, although it is recommended to add it direct in the cyanidation of ores, I prefer hydrogen peroxide. The idea is, that for silver extraction the hydrogen peroxide must be carefully made under ice-cold conditions or no satisfactory results can be expected. The addition of sodium dioxide direct to cyanide with the above object in view is generally a useless proceeding, due to lack of caution in the temperature employed.

TABLE SHOWING COSTS OF OXIDIZING AGENTS.

Chemical product.	Avail-able oxygen, %	Cost, cents per lb.	Cost, efficient oxygen, per lb.	Remarks.
Sodium di-oxide Na ₂ O ₂	20.5	40	2.00	
Barium di-oxide BaO ₂	8.0	8	1.00	
Hydrogen peroxide H ₂ O ₂ — 3%	1.5	12	8.00	
Potassium permanganate K ₂ Mn ₂ O ₈	12.7	10	0.80	
Sodium bi-chromate Na ₂ Cr ₂ O ₇	17.9	7	0.38	
Calcium hypochlorite CaOCl ₂	7.4	1.25	0.17	
Potassium ferri-cyanide K ₃ (Cn) ₁₂ Fe ₂	...	35	...	Indirect agent in oxidation in presence of alkali.
Ozone (O ₃)	...	10	1.10	8 lb. per kw.-day in form of ozonized air.
Chlorine (Electrolytic)	...	4	...	Not crediting caustic soda produced at the cathode.
Ammonium persulphate (NH ₄) ₂ S ₂ O ₈	7.0	60	8.40	
'Linde' oxygen	96-98	30	0.30	With 'Linde' apparatus, cost of 96 to 98% will be 2c. per pound.
Chlorine peroxide Cl ₂ O ₂	31	35	1.14	

Of the permanganates, either calcium or potassium permanganate may be employed, but best in a neutral or alkaline solution and separate or distinct from the cyanide solution, which they would quickly decompose. The best manner of using the permanganates would be in a hot solution, agitating the silver-bearing slime with them while passing steam into the silver-slime tank until decolorization had completely taken place, then pumping the cooled slime to a cyanide tank and dissolving the silver out with cyanide. Manganous salts, as stated in former papers, are injurious in cyaniding silver ores. This is not the case, however, with manganic oxide, (MnO₂), which is a powerful oxidizer, and is applied in the Adair process. Bichromates are claimed to have given good results in the cyaniding of silver ores

through the addition of the oxidizing agent direct to the cyanide. This salt is a mild oxidizing agent, and as such may be useful in some cases. The persulphates have also been tried with the same object in view as well as the percarbonates. If it were not for their cost they would prove valuable. On a large scale ammonium persulphate ought to be produced by electrolytic processes for less than 10c. per pound. I come to the conclusion, however, that the solid oxidizing agents, with the possible exception of the hyperchlorites (chloride of lime), are costly and only to be applied where their consumption is a fraction of that of the cyanide. Air or even oxygen has very slight oxidizing value at the ordinary temperature, and may therefore be dismissed. In view of the development of the electric discharge methods for generating ozone (O₃) which now can be produced at trifling expense, it is surprising that its application as an oxidizer in cyanide treatment has not made greater progress. In the form of ozonized air in which 1 lb. of ozone will require 3 kw. hours to produce it, the cost per pound figures out at about 10c. The system of its production is simple and outside of the original ozone plant does not require a change from modern air-agitating apparatus, which finds its latest application in the Pachuca tank. Ozone is much more effective than the peroxides, and the results with it in cyaniding silver sulphide ores are highly promising.

The most powerful reagent, however, for disrupting and decomposing the group of antimonial-silver minerals without roasting the ore to make them amenable to cyanide, is chlorine. This can be produced economically, together with the neutralizing alkali, by means of the electrolytic chlorine cell. One of the cells, prominent at this time is the Townsend. It is successfully operating at Niagara Falls and other centres, and has also been adopted in some gold chlorination mills. The following data will show the capacity of these cells, their output of chlorine and caustic soda direct from salt brine per 24 hr., the cost of the cells, and the approximate cost of producing the chlorine. The method to be applied in treating antimonial-silver ores by means of electrolytic chlorine is to first slime the ore and in an acid-proof tank, treat the pulp heated by steam, by passing the chlorine into it, until tests indicate that the silver minerals have been thoroughly broken up and the silver transformed into chloride. The antimony and arsenic present will also be converted into chlorides while sulphur will separate out and will subsequently only slightly affect the cyanide. The acid compounds formed in the chlorinated pulp will then be neutralized by adding enough of the caustic soda solution produced at the cathode compartment of the cell, sufficient of the soda being added to thoroughly neutralize and render alkaline the silver-ore pulp. After this treatment the ore will have reached a suitable condition on cooling for ordinary cyanidation. I suggest that a preliminary washing out of the salts remaining in the pulp through this preparatory treatment may be of value in some instances, prior to the final cyanidation.

One of the simplest reactions involved in decom-

posing antimonial-silver minerals by means of chlorine may be expressed as follows:

(Pyrargyrite):

The group of antimonial-silver minerals, is slimed, cannot resist the decomposing effects of chlorine, especially on warming the liquid in which they are suspended, as already shown by Hoepfer, Borchers, Kopp, and other experimenters in electro-metallurgy. Their method, however, was to extract the metallic chlorides formed, as such, by means of brine or calcium chloride, while I propose to use chlorine only as an intermediate means, that is, prior to the final cyanidation. Electrolytic chlorine, due to the low price at which it can be produced at present, offers the simplest solution of the silver cyaniding problem, as it produces the neutralizing agent, namely, caustic soda, at the same time and without any extra expense, and in proportion sufficient to balance the acid compounds formed in the first instance. The gold present in the ore will also be attacked by the chlor-

Apparatus for Producing Ozonized Air.

ine and will the more readily dissolve later in the cyanide.

TABLE SHOWING CAPACITY AND OUTPUT OF TOWNSEND ELECTROLYTIC CHLORINE CELL PER 24 HR.

(Standard 2500 Ampere Cell at 4½ Volts.)

Chlorine, lb.	Caustic soda, lb.	Power required.	Chlorine per hp. lb.
156	177	11¼ kw. or 15 hp.	10.4

Estimating power at ¾c. per horse-power hour, the chlorine will cost approximately per pound for power 18c., for salt (at \$10 per ton) 1c., for attendance and repairs 1.2c.; total 4c. The caustic soda produced as a twin product is not credited in the above figures. The 2500 ampere cell has the following dimensions: height 3 ft., width 12 in., length 8 ft., and it is constructed mainly of cement concrete. The cost of cell is \$575 f. o. b. New York. Townsend cells having 4000 and 6000 ampere capacities have also been constructed and recently placed in operation at Niagara Falls.

In concluding this article I wish to affirm that in both ozone and chlorine will be found the powerful and cheap re-agents which are certain to aid in solving the problem of silver cyaniding. Two economic factors, however, will present themselves, and I must affirm for chlorine, first, that with ores carrying only a small per cent of pyrite, or for those out of which a preliminary concentration has removed the larger proportion of base sulphides, that the chlorine consumed per ton will not exceed the cost of roasting or chloridizing. In most instances it will only reach

a few pounds of chlorine per ton of ore or tailing treated. Second, with acid-proof, alkali and chlorine-proof brick-lined tanks, no trouble need be anticipated in the effort to thoroughly attack the silver-bearing minerals by chlorine, and in an ore-pulp heated to 120-150° F.

Ozonized air is now used industrially in a large number of chemical industries and particularly in the purification of drinking water. Its cost of production is being reduced to such an extent as to make its application in silver cyaniding a very small factor in the total cost of treatment. A large number of forms of ozoning apparatus have been patented. One of these in successful operation in a number of works produces 155 gm. of ozone (O₃) in the form of

Townsend Electrolytic Chlorine Cell.

ozonized air per kw. hour, of 8 lb. per (24 hr) kw. day. In the cyanidation of silver, where the ore assays on an average 20 oz. per ton the oxygen required would be one-fifth of this, or 4 oz. For 100 tons of ore per day this would equal a total of 400 oz. of ozone, or 25 lb., which in practice would be met by a 4 to 5-hp. ozone-producing apparatus.

The reaction of silver sulphide with ozone and cyanide may be stated:

Only ordinary cyanide apparatus will be required in the use of ozone, that is, no brick-lined or acid-proof tanks are needed, as is the case when chlorine is to be applied.

The importance of manganese in the manufacture of steels of all kinds, and its influence upon high-speed steel in combination with tungsten is very great. Like nickel and chromium, manganese seems to hinder the formation of the double carbides of tungsten and molybdenum. Steel containing these elements in combination with a sufficient proportion of manganese (or of nickel or chromium), therefore are self-hardening without the high heat treatment, though they are not necessarily high-speed to any considerable extent, even when they receive that treatment. Very high manganese makes steel cold-short (brittle when cold) and susceptible to fire cracking.

SYSTEMS OF CHARGING FOR ELECTRICAL ENERGY.

By W. T. RYAN.

*Within the last few years systems of charging for electric current have been widely discussed. The principal ones in use at the present time may be classified as follows: 1. Flat rate. 2. Meter. 3. Classification of rates. 4. Wright maximum-demand system. 5. Doherty rate. 6. Four C system. 7. Double-rate meter. 8. A charge based on the customer's minimum monthly guarantee. 9. Combinations of the above.

1. The flat-rate system. Many companies supply current at a certain price per month per lamp. This works out to rates per kilowatt-hour, varying from a minimum where the current is used continuously to a maximum of infinity where no current is used. This system is popular because the customer knows just how much he will be called upon to pay. Book-keeping is simplified, and the cost of meters is avoided, but the rate is unjust and void of business principles.

2. The meter system. This system to many customers appears equitable. An analysis shows a fixed charge per unit of energy sold, regardless of capacity demand. In this case the 'cost to produce' varies from low per kilowatt-hour, if the total capacity be used continuously, to infinity if no energy be used. The system is as absurd as the flat-rate system; neither bears any relation to the cost of service. If as much as \$1 per kilowatt-hour were charged some customers, their total payment would still be so small that it would not equal the cost of reading their meters, keeping books for their accounts, and the core-loss of transformers, to say nothing of the interest, depreciation, taxes, and insurance on the money invested in apparatus.

3. Classification of rates. A common method is to classify customers according to their daily use of current, and to establish a separate rate per kilowatt-hour for each class. There are two distinct classes of service in most electric plants, namely: (a) domestic lighting, with its negligible demand during the day and its excessive demand for current during the evening; (b) motive-power service, with a nearly uniform demand. Customers of the first class are charged at a higher rate than those of the second class. In addition to those differences in the scheduled prices, quantity discounts are often given, and in many cases there is also provided a minimum charge to meet interest on the cost of the watt hour meter, cost of reading it, and a portion of the cost of the station bookkeeping.

4. Wright maximum-demand system. No adequate method of storing electrical energy economically is in existence. This necessitates keeping in readiness, at all times, the apparatus of the station, which is loaded to full capacity for only a short interval each day during the busy part of the year. This requires a corresponding investment, on which a reasonable return for interest, insurance, depreciation, and taxes must be obtained before any profit

can be made. On the straight meter rate, or even with a classification of rates, it is practically impossible to charge the short-hour customer a sufficiently high rate to cover the expense. A number of systems intended to make each customer pay in proportion to the 'cost of service' have been devised. Arthur Wright, of England, divides the cost of electrical energy into (a) preparation costs, (b) production costs. The preparation costs are again subdivided into (1) formation expenses, (2) stand-by costs, (3) service costs. (a) The 'formation expenses' are those incurred by the necessity of obtaining the initial capital to start the undertaking with. The 'stand-by costs' represent the maintenance of the plant and supply-mains in a condition ready to supply and distribute energy. The 'service costs' represent the maintenance of service wires and meters, the incidental disbursements connected with accounts, complaints, and collections. (b) The 'production costs' represent the actual expense of supplying and distributing electrical energy. This varies with the amount of energy generated and distributed. The unit of production cost is the 'increment of expenditure' incurred by making a given plant and set of mains supply an extra unit of electrical energy. The system assumes that each customer should pay the fixed charge on the portion of the plant he uses, and in addition should pay the running expenses only for the hours he actually uses the plant. The Wright maximum-demand meter, which records the maximum current used by a customer between two readings, is read at the same time as the watt-hour meter. These readings show the amount of energy to be charged for at a high rate, and the amount at a low rate. Other methods which are sometimes used are: (1) by putting the demand equal to the connected load; (2) by estimating the demand; (3) by limiting the demand so that a customer cannot exceed a certain amount; (4) by measuring the demand. The advantages and disadvantages of these methods are as follows: (1) Connected load; no maximum-demand meters; demand fixed in advance; unfair basis; notifications and inspections necessary; inaccurate determination; large connected load discouraged. (2) Demand estimated; fair basis; no maximum-demand meters; demand fixed in advance; notifications and inspections necessary; inaccurate determination; large connected load discouraged. (3) Demand limited; fair basis; notifications and inspections not necessary; accurate determinations; large connected load not discouraged; instruments necessary. (4) Demand measured; fair basis; notifications and inspections not necessary; accurate determinations; large connected load not discouraged; instruments necessary; demand not fixed.

The charges may be arranged in several ways. One method is to charge a list price per kilowatt-hour, and then give discounts to customers who average two or three hours per day use. Another method is to charge a fixed amount per year, payable in twelve installments as rent on the investment. In addition, a charge of 3 or 4c. per kilowatt-hour would cover the running expenses. The most common method is to charge, say, 12c. per kilowatt-hour for the 60

hours (2 hours per day), and, say, 4c. per kilowatt-hour for the remainder.

5. Doherty rate. According to Henry L. Doherty, the costs are fixed: (1) by the number of customers; (2) by the distance of the customers from the station; (3) by the capacity they demand; (4) by the amount of their consumption. There would seem to be no reason for varying the cost to different customers because of distance from the station, except in extreme cases. Certain costs are entirely fixed by the number of customers. To cover these there should be a fixed charge for each customer. Costs such as interest, insurance, depreciation, and taxes, which are fixed by the capacity demanded, are covered by a 'stand-by' charge. Still other charges are fixed by the quantity of current generated, such as fuel, oil, lamp renewals, etc. To cover these there should be a fixed rate per kilowatt-hour consumed. The maximum demand on a station is usually from one-third to one-half the load connected. The cost of the station and the lines leading from it usually lies between \$200 and \$600 per kilowatt installed. A fair value for the stand-by charges, which include interest, insurance, depreciation, and taxes, would be 12%. A fair value for the fixed charges, which include office expenses, reading meters, rendering bills, etc., would be, say, 3%. If the plant costs \$400 per kilowatt installed, and the maximum demand is one-half the connected load, the annual stand-by charges plus the fixed charges would be \$30 per connected kilowatt. If a customer uses 50-watt lamps, the annual stand-by charge, plus the fixed charge per 50-watt lamp connected, would be \$30 divided by 20, or \$1.50. This would be 12½c. per month per equivalent 50-watt lamp connected, whether the customer uses any power or not.

6. Four C system. This system involves a capacity charge and a current charge—four Cs. The average cost of capacity of the plant is found by the formula: $C = \frac{F}{N}$, in which F = fixed charges per annum on unit cost of plant; N = number of 50-watt lamps per unit; C = average capacity charge per annum per lamp. After obtaining the average capacity charge, a maximum and minimum charge per lamp is determined on a sliding scale. In this system the fixed charges include all except production costs, and are apportioned among the various customers in proportion to the length of time they use energy. Any system which charges as much rental to a short-hour as to a long-hour customer discourages the growth of the industry. While it is consistent to expect the customer to reimburse the station for fixed charges necessary to furnish the service required, this is necessary only to insure the station against loss in carrying capacity for him. It is not necessary or desirable to charge the full amount in order to get this protection.

7. Double-rate meter. The double-rate meter is an ordinary watt-hour meter, equipped with two sets of dials and a clock which throws into gear one set during the period of excessive loads and another during the remainder of the 24 hours. The customer is charged a high rate per kilowatt-hour for the energy indicated by the first set, and a low rate for

the energy indicated by the second. Such a system promotes long-hour consumption. An ordinary meter may be used by inserting a resistance in an auxiliary circuit at the central station, when the low rate is to begin, and maintaining it until the end of the period. This retards the meter to a degree representing the ratio the low rate bears to the high rate. This method reduces expense, but has the disadvantage of not being easily understood by the average customer. The chief difficulties are the absence of suitable mechanical appliances by which two meters or two sets of dials can be controlled in such a manner as to protect the company against fraud, secure accuracy, and avoid increase in fixed charges. While this method tends to broaden the peak, it also tends to reduce the use of light in the business districts at a time when the rate would be doubled or tripled.

8. A charge based upon the customer's minimum monthly guarantee. In a recent bulletin published by the Union Electric Light & Power Co. of St. Louis a novel system of rates is explained. Under it the service is divided into a large number of classes, and each customer in the same class gets the same rate. The rate is based on the minimum monthly guarantee the customer is willing to make per horse-power or per 50-kilowatt lamp connected. The rate is also lower the larger the connected load. The power rates are on the same plan. A customer whose connected load is one horse-power pays 10c. per kilowatt-hour if he guarantees \$1 per month per horse-power. If he guarantees \$7.50 per month per horse-power, he pays 5c. per kilowatt-hour. There are a number of intermediate steps between the 5 and 10-cent rates, depending on minimum monthly guarantees. This system has marked advantages. It is difficult for customer A to say that there is discrimination in favor of customer B, for if A will connect the same load and make the same guarantee as B, he will get the same rate. It strongly encourages larger connected loads and longer hours use of both light and power by all customers at all times.

9. Combinations of the above systems. Many central-station managers find it necessary to work out systems which are combinations of two or more of the above. It is very difficult to work out a system of charging for electrical energy which will be fair and equitable, easily understood by the layman, and at the same time induce all customers to increase their consumption economically to themselves and with profit to the generating company.

With the aid of titanium it is said to be possible to make better rails from bessemer converter steel than without its aid from open-hearth steel. With the aid of titanium it is possible to eliminate blow-holes. It is further possible to remove the brittleness and increase the durability of chilled-iron car-wheels, and further, to improve nickel steel, chrome and nickel, and other steels.

Tests by the Brinell method show that chilled cast-iron treated with titanium is harder than the untreated metal, although the chill is reduced by the alloy, and yet gray iron back of the chill is readily machined, such as hubs of car wheels and the like.

CENTRIFUGAL PUMP EFFICIENCY.

Written for the MINING AND SCIENTIFIC PRESS
By V. V. MESSER.

The simple principle involved in the construction of a centrifugal pump is the great argument in its favor. Invented about half a century ago, the centrifugal pump retains the form originally adopted by the inventor; the evolution of the pump always has affected details of construction only. Latest developments of centrifugal pumping machinery with hard-metal wear-resistant liners have made it possible to use centrifugal pumps for handling extremely gritty liquids, and the most modern metallurgical practice indicates that tailing wheels and elevators are doomed to give way to centrifugal pumps for elevating sand and tailing. Finally, the advent of multiple-stage centrifugal pumps has broadened their field of usefulness, so that even now the most approved types of plunger pumps find a formidable competitor in the multiple-stage centrifugals.

It is impossible to obtain exact figures as to the number of pumps in use in this country, most of which are designed by practical builders by rule of thumb, or are copied blindly from a pattern of some of the so-called standard makes. Consequently, the efficiency of the average pump is invariably low. Figures as to the money wasted in this country annually by ignorance in the building of pumps would give simply appalling results.

An inefficient pump is an expensive machine, even if the first cost be nothing. Indeed, the first cost is an insignificant item when placed beside the cost of power required to run it during its life. For example, suppose a 2-in. pump of low efficiency is bought at a cost of \$50. Suppose 2 hp. be required to run it, and that the cost of power is \$12 per hp.-month. At the end of five years \$1440 will have been spent for power. Comparing the cost of the pump with the cost of power, we find that the first cost was only 3.3% of the total expenditure.

Table Showing Cost of Pumping 1000 Gal. of Water per Minute in 30 Days.

The upper horizontal row of figures in the accompanying table gives the cost in dollars and cents of running a 6-in. centrifugal pump delivering 1000 gal. of water per minute against a head of 20 ft., with different pump efficiencies, ranging from 30 to 75%, assuming that the cost of power is 2¼¢. per 1 kw.-hr., or \$12 per hp.-month. These figures are of course arbitrary. It is a simple matter to arrive at the cost

with different heads, cost of power, etc., since the cost will vary in direct proportion. The figures given represent a fair average for power at a great number of mines.

The triangular table gives the saving effected in 30 days by using a pump of higher grade. To compute this, find the efficiency of a pump of the higher grade in the upper row and that of the lower-grade pump in the vertical column; follow their respective lines vertically downward, and to the right horizontally, until they meet; the result will be the saving effected in 30 days of continuous pumping under conditions mentioned. Thus a 60% efficiency pump would save \$50 in 30 days over a 40% pump. The table also shows that a 40% efficiency 6-in. centrifugal pump consumes \$150 worth of power per month to deliver 1000 gal. of water per minute, which is little below the first cost of a standard 6-in. pump.

An ideal centrifugal pump would be a machine in which the molecules of liquid enter the pump-casing at a slow speed and are then accelerated gradually

Fig. 1.

to such a velocity that they would acquire momentum to rise to the delivery point, losing all this momentum through the force of gravity on their travel up the discharge line, at the terminal point of which they would leave it with no velocity. The simplest mechanical analogy is a solid body thrown upward in a vertical direction. Its momentum will be absorbed by the force of gravity, and finally, when all of the energy has been absorbed, the body will come to rest at the highest point of its travel. If that point be the height to which the body is intended to be lifted by the machine, that would represent the condition of 100% efficiency.

Evidently there will be different pressures at the circles of different radii on the runner, and ideal conditions require that there be no probable leakage of liquid in a radial direction between two points on the runner of a pump. That supposes absence of friction, which is not attainable. Actually, energy is wasted by the thrashing or churning effect of the runner. Let Fig. 1 represent a typical cross-section of a centrifugal pump. Let D be the outside diameter of the runner in inches; d the diameter of the suction-pipe in inches; m the width of the runner in inches. Then the liquid as it flows through the pump,

instead of being accelerated evenly, is being retarded inside of the casing and 'thrashed'. It is retarded because the cross-sections through which the water passes as it flows in radial directions is invariably greater than the cross-section of the suction-pipe. It takes a certain time for the liquid to pass through the runner. In the case of a runner of equal width (Fig. 1), the time in which liquid passes through the runner is expressed by the formula,

$$T = \frac{\pi m}{4Q} [D^2 - d^2];$$

where T = time; Q = capacity of pump in cubic inches per second; $\pi = 3.1416$; D = diameter of runner; d = diameter of suction; and m = width of runner.

Taking a 3-in. pump, in which $D = 14$ in., $d = 4$ in., $Q = 850$ cu. in. at 700 r.p.m. Using this formula, we have figured that the time required for a molecule of liquid to pass through the runner is 0.33 second. In that length of time the runner will make about $\frac{1}{2}$ to 1 revolution of a pump would suffice to pass the water through the runner without whirling the liquid and churning it. The frictional effect of the churning plays an important part in the power bill.

Fig. 2.

Another source of loss in efficiency is the continuously increasing clearance between the runner and the casing. That loss can be decreased by using a hard-metal liner, but that is not a remedy. The wear itself must be taken up. The importance of having the smallest possible clearance between the runner and the casing is obvious, for the reason stated. Nobody would think of running a piston pump having a clearance around the piston, while many a mill-man would run a centrifugal pump with $\frac{1}{8}$ in. clearance on each side of the runner and never think of the continuous power-loss he was occasioning by reason of it.

The centrifugal pump has a special field of usefulness which cannot be filled by any other type, and to get efficiency the runner should be designed for the pressure the pump is to work against. Therefore, the ideal pump should have the runner easily accessible, and the vendor should be prepared to equip each pump sold with a runner designed for the maximum efficiency at the pressure the pump is to work against. It should not be inferred that a runner designed for a 10-ft. lift will not pump against a 20-ft. lift, but it will not develop its full efficiency

except when working under the head for which it was designed. A centrifugal pump properly built for a given purpose can be operated so as to develop an efficiency in smaller sizes (3 to 4 in.) as high as 60%, and in sizes larger than 6 in., about 70 to 80%. In general practice, pumps up to 4 in. diam. of discharge are usually developing 30 to 40% efficiency, and larger sizes are doing but little better. There is no simple way of accurately ascertaining the efficiency of a centrifugal pump, but there are many ways of determining it approximately, that is, within 2 to 4%. The following method may be used with practically no special appliances; all that is necessary is a couple of springs, set-screws, and a shaft-collar. First, measure the flow of water pumped, in miner's inches, using $1\frac{1}{4}$ -in. plank, aperture 2 in. wide, centre line of which shall be 6 in. below the surface. The miner's inch, thus measured, will be equal to $1\frac{1}{2}$ cu. ft. per minute, or $11\frac{1}{4}$ gal., of $93\frac{1}{2}$ lb. of water. Multiply $93\frac{1}{2}$ by the number of miner's inches measured, and by the elevation of the point of discharge above the level of the water in the vessel to which the suction-pipe is connected. The product will represent the theoretical foot-pounds of energy

Fig. 3.

necessary to elevate a given amount of water per minute. Now, if we determine the number of foot-pounds of energy actually consumed by the pump, the ratio of the former to the latter, multiplied by 100, will give the efficiency of the pump. If the pump is run by a motor or gas-engine, then by using a watt-meter or Prony brake it is easy to arrive at the figures; but if it is run from a line-shaft, loosen up the driving pulley on the shaft by removing the key or set-screw, put another wooden pulley next to the loose one (Fig. 2), and set the new pulley tight. Then take two tension springs and connect the pulleys by the springs, as shown in Fig. 2. See that the spring-tension be in a direction exactly perpendicular to the shaft; otherwise the tension of the springs will cause side-pressure, which will result in friction between the pulleys, thus rendering the observations worthless. Nail a few pieces of leather, P, on the face of the wooden pulley, and set a metal collar next to the loose pulley. The collar, C, is to be provided with a screw, S, with a catcher, D. When the shaft is turning, put an iron bar in the way of the travel of the catcher, D, which will work the screw and clamp the pulleys together. When the pump is working, the

tension of the belt is taken by the springs, and the loose pulley will be turned on an angle in proportion, or nearly so, to the tension of the belt. Count the revolutions of the shaft. After the shaft has been stopped, mark the relative position of the pulleys, and then slacken the screw, C, after which nail a wooden plank, f, Fig. 3, to the wooden pulley; see that it does not disturb the free balance of the pulley. Nail it in the middle, and then by hanging weights on the plank and turning the shaft and leaving the level, f, horizontal, bring the pulleys to the same relative position they held in relation to each other while the pump was working. Then multiply the weight, N, in pounds, the horizontal distance, G, between the centre of the shaft and the vertical line passing through the weight in inches, by the number of revolutions, and by 6.28, and the result will give the foot-pounds of energy consumed in one minute by the pump. Then figure the efficiency in the manner mentioned above. The 'slip' of the belt, if moderately tight and dressed, will be about 1 to 2%. Repeat the measurement several times to get an average. If your belt runs smooth, the average of three observations will do; if it runs unevenly, which is the case with gas-engine drive, then make at least five to seven observations and take the average.

This method can be used to determine the horsepower consumed by any smoothly running machine. See that the driving pulley does not run too fast, otherwise the centrifugal force may affect the tension of the springs. See also that the springs are as light as possible, but do not overstrain them or inaccurate results will be obtained.

CEMENT PRODUCTION IN 1908.

The total production of all kinds of cement in the United States during 1908, as shown by returns received by the U. S. Geological Survey from all the cement producers of the country, amounted to 52,775,925 barrels, valued at \$44,376,656. This total was made up as follows:

	Barrels.	Value.
Portland cement	51,002,612	\$43,472,679
Natural cement	1,621,862	808,509
Puzzolan cement	151,451	95,468
	52,775,925	44,376,656

The corresponding figures for the calendar year 1907 are given below for purposes of comparison:

	Barrels.	Value.
Portland cement	48,785,390	\$53,992,551
Natural cement	2,887,700	1,467,302
Puzzolan cement	557,252	443,998
	52,230,342	55,903,851

The portland cement production showed a heavy decrease in 1908 as compared with 1907 in most of the Eastern and Southern States, the loss being greatest in Pennsylvania, New Jersey, New York, and Michigan. This decrease in the East and South was offset, however, by remarkable gains reported by plants in the Middle West and on the Pacific Coast. The average price of the entire portland cement output in 1908 was only 85c. per barrel—36c. below the average price in 1907.

PURIFYING SMELTER SMOKE.

*The testimony of E. P. Mathewson in the final hearing before Judge Hunt in the United States Circuit Court of the ninth district of Montana, in the famous smelter-smoke case (*Bliss v. Anaconda Copper Mining Co.*), is of interest. It passes in review the methods available for abating the difficulty. Mr. Mathewson, the manager of the Anaconda Copper Co., testified that the method of cooling by the admission of air into bag-houses is an impracticable way, because the gas in the smoke would destroy the bags as fast as they could be supplied. The bag-house method is successful in lead and zinc smelters, but, owing to the quantities of acid in the fume from copper smelters, it is impossible to prevent the destruction of the bags. He also explained a radiation process, saying that as the methods now employed in the Washoe smelter caught all the particles except the finest, the radiation process would apparently not be effective to catch the particles that are not now being recovered. He also referred to a freezing process, but that could only be used by counting upon a very large product of poisonous mud which could not be left exposed without great danger. Where the quantity of mud produced by this process is small it can be buried, but at the Washoe smelter, owing to the enormous amount which would result, burial would be impossible.

In regard to the electrical discharge method, Mr. Mathewson made it quite clear that, owing to the mechanical difficulties encountered thus far, practical application of the process, as attempted in California, had not been a success, and could not be made effective at the Washoe, where the velocity of the gases is approximately twenty times greater than at the Selby smelter on San Francisco bay. F. G. Cottrell, Professor of Physical Chemistry in the University of California, the inventor of this process, visited the Washoe smelter, and after study of the conditions there was not willing to assure defendants of its success without further experimentation.

Mr. Mathewson also explained the friction or wire process now being constructed at the Boston & Montana copper smelter at Great Falls, Montana. The process consists in suspending thousands of wires from the ceiling of large chambers in such a way as to cause friction of the gases, and thus bring about a settling of the dust. Mr. Mathewson himself doubts the success of this experiment, but says that if its efficiency is demonstrated it will be used at the Washoe smelter. He expects final tests to be made during this year.

Another system explained at the hearing is the filtering of the gases through finely pulverized slag moistened with water. This, the writer said, would also result in the production of immense quantities of poisonous mud, and, moreover, has not been successful in Utah, where it has been tried. The feasibility of decreasing the velocity of the gases was explained. This method, he said, would require the construction of a flue twenty times as great as the

*Abstract from testimony given by E. P. Mathewson, before the U. S. Circuit Court in Montana.

present Washoe flue to decrease the velocity to 60 ft. per minute. By this device the product recovered would be dust, but, comparatively speaking, the excess over that now saved would be so slight as not to make the process worth serious consideration. The use of centrifugal gas-cleaners was mentioned, but that process would also mean the accumulation of great masses of acid-mud, and thus involve the same problem of its disposal. Mr. Mathewson closed his testimony by saying that the result of his own study and of the extensive investigations and experiments made by engineers and scientists in Europe and America in behalf of the defendants, is that the Washoe company has a system nearer perfection than any other yet devised for the purpose of treating arsenic fumes. He added, however, that he knew the system was not perfect, and that the defendants were still experimenting and would continue to study the question.

BLASTING AND PREPARING THE SHOTS.

Written for the MINING AND SCIENTIFIC PRESS
By DENNIS H. STOVALL.

I know a mine superintendent who has made it a practice to question every miner he employs regarding his familiarity with blasting. Moreover, he gives them instruction when necessary, in this important matter, and he maintains a uniform system. By exercising a little care he has had few accidents. This is a feature of practical mining to which every superintendent and manager should give attention.

Few miners use any explosive other than dynamite, though some still cling to black-powder, especially those working in soft ground. Some large companies still use black-powder, believing it more economical and safer. Whether it be safer or not depends much upon the way in which it is used. It requires more tools and considerably more time to prepare a shot with black-powder than with other common explosives, but the results are satisfactory if the powder be carefully set and well tamped. The tools needed are a pricker or needle, which is a slender tapering rod of copper or bronze, used for maintaining a hole in the tamping through which the charge can be fired; the tamping bar, which is a rod of iron, copper, or bronze, or of iron shod with copper, and used for ramming in dried clay or pounded slate, to hold the powder firmly; and a claying bar, used for lining wet holes with clay, to render them temporarily water-tight.

Where loose powder is used, the ordinary method is to set in the pricker, holding it upright in the centre of the hole while a portion of the charge is poured in. Care is taken to draw out the needle as the tamping proceeds, so as to obviate too much exertion being required for its final withdrawal. The small hole left in this way serves for the insertion of the fuse, or of the quill or straw filled with powder, which is pushed down and connected with the fuse proper. The best and surest method, however, is to push the fuse itself well down into the hole. As the safety-fuse burns slowly, not faster than two or three feet per minute, the miner has ample time for retreat, by allowing sufficient length. It is usual to light the

fuse by a candle-end fixed under it by a piece of clay, considerable time being required for the candle to burn through the fuse.

Most modern high explosives contain nitro-glycerine in some form, the explosion being brought about through the action of a fulminating cap. Gun-cotton is employed extensively in western mines, and is prepared in various forms, the cotton fabric itself being always mixed with some nitrate or mixture of nitrates. Gun-cotton is more powerful than gun-powder, though less powerful than dynamite; it possesses an advantage over the latter, however, in that it does not have to be thawed in cold weather. It can be handled with greater safety than dynamite, but is just as dangerous when remnants are left in partly exploded charges. The miner should examine the bottoms of all holes after blasting, and destroy any remnants of powder by firing a detonator in a 'socket' or missed hole which cannot with certainty be pronounced free from danger.

The methods employed for firing gun-cotton, cotton-powder, blasting gelatin, dynamite, and all explosives containing nitro-glycerine, are practically the same. The explosion is induced by the detonation of a fulminating cap. This fulminating cap contains fulminate of mercury with chlorate of potash, and it is fastened into the safety-fuse by squeezing with a pair of nippers. It is then inserted into a small cartridge, or primer, of the explosive, and placed above the charge proper. Some miners who use gun-cotton prefer to lightly tamp in a small charge of gun-powder above the cotton, firing it through this.

The common stick-dynamite has several advantages over other forms of explosives. It has greater power, may be used in wet holes or under water, is effective in ground which is full of cavities, and it requires no tamping. Being plastic, because of its mixture with wood-pulp, it readily adjusts itself to completely fill a hole after it is placed. The greatest disadvantage of dynamite is that it must be thawed in cold weather, but where care is exercised this can be accomplished with comparatively little danger. There is also its freakishness, by which entire sticks fail to explode through the action of the fulminating cap, but may later ignite with fatal results when struck with a bar or drill. The danger is enhanced when remnants have been left in contact with water, as the liquid causes a separation of the nitro-glycerine from the dope, so that even a blow upon the adjacent rock leads to an explosion. A small quantity of the nitro-glycerine leaked into a crack is sufficient to cause death and destruction.

Firing several holes simultaneously by electricity eliminates much danger. There has been placed upon the market an igniter by which a number of instantaneous fuses convey fire to as many separate holes. The charges are fired, either singly or simultaneously by electricity, the electric charge being obtained from a magneto dynamo or battery. The distinct advantage of this method of firing is its safety, as the miner can retire to a perfectly safe place, and all the miners can reach a place of safety before a single shot is exploded.

ANTHROPOMORPHISM IN PETROGRAPHY.

By EDWARD K. JUDD.

*If some of you have been casting curious glances at that word 'anthropomorphism', perhaps you have suspected that it was a misprint for 'metamorphism', which is a better known word in connection with petrography. And your suspicion is quite defensible, because a trivial typographical error like that would be well within the capability of any compositor. But no, it is not a misprint. I selected that title because the printer had a job-lot of type that he wanted to use.

Then, too, what a splendid reference horizon it makes from which to measure the stratification of this evening's entertainment up and down. What a sense of security the preceding speakers must have felt when they saw this solid substratum under them, even if it is only barren measures. You will notice, too, that it has both of the elements of a good reference horizon, in that it is easily recognizable and is continuous for a great distance.

But to come to the point. Have you ever considered how frequently we employ the terms of the geologist to describe members of the human race, but how seldom the operation is reversed? We say, for example, that when the object of a young man's affection gets the marble heart and gives him a stony stare, it is apt to make him feel pretty rocky. But, if he is sensible, he will soon get over it and, finding a new object for his attentions, will begin to write sonnets on her sapphire eyes, sparkling like diamonds; on her pearly teeth and her silvery laugh; on her coal-black, or it may be, her golden tresses, according to the prevailing fashion. We say that John Smith has a sandy complexion and is a regular old skin-flint. When the Chicago pitcher sends the New York batter to first base on four balls, we quite properly shout 'glass arm' at him. And finally, when you were a barefoot boy in the country, didn't you think that your grandmother was a gneiss old lady because she appreciated your appetite? And so it goes; you see how incessantly we have to go to the mineral kingdom for similes and metaphors.

Now I propose to reconstruct the science of petrography on an anthropomorphic basis. How much more pleasant it will be to think of the rocks as having personalities, characteristics of soul and spirit as well as of body. When we pine for amusement, instead of going down-town to a poor show, we will come up here and become brothers of the no longer insensible rocks.

To go about this we only need to take the adjectives now employed in describing the minerals and translate them into terms applicable to the description of a human being.

To begin with the colors, we suspect a man whose face is always red of being bibulous; a green man is either unsophisticated or an Irishman; when a man is blue, he is melancholy, and, of course, yellow and brown are respectively blonde and brunette. Apply-

ing the same method to the shapes of minerals, a square man is an honest man; a round man is corpulent; rectangular means blockheaded; and prismatic means slab-sided; we would call a lath-shaped man spindle-shanked, while a man may be short in any one of three ways: He may be short in his accounts—a defaulter, or a man of small stature, like Bildad the Shuhite—a sawed-off, or he may be short like St. Peter, when he said, "Silver and gold have I none," meaning impecunious. Just to translate a few more of the terms of mineralogy into those of anthropology, a soft man is a mollicoddle; an elastic one is a rubber-neck; a flexible one is double-jointed. Dense means thick-headed; coarse means vulgar; while delicate means ladylike. We speak of a porous man as being a sponge, or a grafter, and if you meet a smooth man, you ought to watch him, because he may be a swindler, especially if he has a magnetic attractive personality. A hard man, that is, one hard to get along with, is generally cranky, and a brittle man, one who goes broke easily, is a spend-thrift.

Now let me illustrate how the new terminology works. Suppose we describe Mr. Fluorite. He is an honest but blockheaded mollicoddle, generally broke and given to fits of melancholy. Mr. Quartz is a slab-sided old fellow with a pale complexion; he is cranky and thinks he is sharp, but you can generally see through him. Sometimes our new nomenclature affords pleasing results, as when we describe Miss Augite as a slender, honest, ladylike brunette; at other times, not so much so, as when we describe Mr. Biotite as a rubber-necked double-jointed Ethiopian, such as you have all seen with his head poking through a hole in a curtain while paying a visit to Coney Island.

Now when I first proposed this system to Professor Kemp, he was wild with enthusiasm; he hurled his now obsolete 'Handbook of Rocks' into the wastebasket; he sat down and began to write furiously on the new edition. By his courtesy I am permitted to read to you a couple of paragraphs from this forthcoming book, entitled 'My Brothers the Rocks and How to Recognize Them Without the Use of the Opera Glass'.

Granite.—Granite is a group of four persons. Besides Mr. Quartz, whom I have just described, they are: Mr. Feldspar, who is a portly gentleman, convivial in his habits, and with a milder disposition than Mr. Quartz; Mr. Muscovite, a Russian nobleman who, though he lacks the ruddy glow of outdoor exercise, is a man of marked flexibility and agility; and lastly, Mrs. Pyroxene, a tall slender lady with a striking brunette complexion.

Diabase.—Diabase is a crowded assembly of spindle-shanked white men and fat darkies. Diabase may be likened to a Fifth avenue stage in which all the seats and most of the standing room are occupied by John D. Rockefeller, Joe Cannon, Tom Platt, and others of their build; when the stage stopped at the next corner and Taft and Santa Claus tried to get on, they had to squeeze in as best they could.

Gentlemen, I recommend you to get a copy of this book as soon as it appears.

*A speech delivered before the Journal Club, Columbia School of Mines. Published by courtesy of the President of the Club.

COMPANY REPORTS.**PODEROSA MINING COMPANY.**

The report of this copper mining company, operating in the department of Collahuasi, Chile, covers the period of six months ending June 30, 1908. Shipments of ore from the mine to the port of Mejillones amounted to 12,156 tons, averaging 29.9% copper, as compared with 5896 tons of 22.7% copper for the previous six months. The development work accomplished was 670 metres, or sufficient to maintain the ore reserves at 100,000 tons, which the general manager, Robert Hawxhurst, reports as containing an average of 25% copper. The balance-sheet shows the satisfactory profit of £84,923, from which dividends of 25% on the capital were paid, amounting to £60,000; while £15,000 was credited to the reserve fund, leaving £9923 to be carried forward.

NORTH BUTTE.

The fourth annual report of this company, which owns mines at Butte, Montana, covers the year ending December 31, 1908. Owing to the fact that the Washoe smelting plant was closed down till March 1, active operations were confined to 10 months. In that time 422,878 wet tons were mined and 413,582 dry tons smelted. The first-class ore amounted to 35.4, and the second to 64.6%. The recovery yielded 36,929,028 lb. fine copper, 1,283,761 oz. silver, and 1593 gold. The average content of the ore in copper was 89.3 lb. per ton treated. The average prices received were, copper 13.3c., silver 51.7c., and gold \$20. Three dividends, aggregating \$1,200,000, were paid; \$19,696 was charged to construction account; and the cash on hand increased from \$174,773 to \$582,466. No estimate of ore reserves is given, though A. C. Carson, general manager, says: "The two new levels that are being opened up should give a large reserve of good ore, and thus insure the present rate of production for several years to come."

GREENE CANANEA.

This is a holding company organized by T. F. Cole and associates to acquire the stock of the Greene Consolidated Copper Co. and of the Cananea Central Copper Co., having mines in Sonora, Mexico. The Greene Cananea is capitalized at \$60,000,000, of which 2,500,000 shares, having a par value of \$20 each, were set aside to be exchanged for the stock of the subsidiary companies, on a basis of 1½ shares for each share of the Greene Consolidated and 1¾ for each share of the Cananea Central. Up to March 16 last, 934,774 of a total issue of 1,000,000 shares of the Greene Consolidated had been acquired, and 552,868 of the 600,000 shares of the Cananea Central. No dividends were paid during the year, and the expenses of the parent company were met by means of a loan of \$25,000 made to it by the Cananea Central.

ROUND MOUNTAIN.

The properties of the Round Mountain Mining Co. are in Nye county, Nevada. They include principally quartz claims discovered in the course of hydraulic operations carried on by the Round Mountain Hydraulic Mining Co. The Round Mountain Mining Co. is at the same time one-fifth owner of the Hydraulic company, which is now in the hands of a receiver. The work on the quartz claims was pushed in 1908, a total of 6775 ft. of development having been done. The available ore reserves include 39,902 tons, which, calculated on the basis of average mint returns for the last two years, \$12.30 per ton, are valued at \$490,794. On this basis the reserves have been increased during the year \$88,294. The net profits to April 1 have amounted to \$271,997, of which \$127,901 has been distributed as dividends on the capital stock of \$1,000,000. During the year 29,582 tons were milled, at a cost of \$6.07 per ton and with a total profit of \$169,889.

NIPISSING MINES.

The Nipissing Mines Co., incorporated under the laws of Maine with 1,200,000 shares having a par value of \$5 each, owns the capital stock of the Nipissing Mining Co., Ltd., which in turn owns 846 acres near Cobalt, Ontario, including

the famous Nipissing silver mine. According to the Fourth Annual Report, the Mines Co. in 1908 paid \$840,000 dividends, with an administrative expense of \$23,323. The Mining Co. paid the Mines Co. \$860,000 in dividends. This was derived from shipments of 3504 tons of ore having a net value of \$1,363,783. Of this ore 78% was high-grade; 15.8 low-grade silicious, 1.4 low-grade cobalt, and 4.8% nuggets. The average assays were: high-grade ore, 3155 oz. silver, 10% cobalt, 5.48 nickel, 37.69 arsenic; low-grade silicious ore, 209.9 oz. silver; low-grade cobalt ore, 97.8 oz. silver, 10.59% cobalt; nuggets, 18,380 oz. silver. The average price received for the silver was 51.97c. per oz. The cost of producing silver is given as \$0.207 per oz. With regard to ore reserves, R. B. Watson, general manager, says: "The estimation of ore reserves in these rich narrow veins will always be unsatisfactory, due to the wide variation both in value and in width, which sometimes takes place in a short distance. It is not economical to completely block out the ore, and heretofore stoping operations have closely followed development, so that the mine has never shown development commensurate with its annual production." In the estimate submitted a total of \$1,078,392 is listed by veins.

CINDERELLA DEEP.

The properties of the Cinderella Deep, Ltd., are in the East Rand district, Transvaal, and include the deep horizons of the reefs worked in a portion of the East Rand Proprietary Mines. The capital stock consists of 100,000 shares of a par value of £1. Crushing began in September 1908. Up to December 31 the mill had treated 33,329 tons, yielding a gold recovery of £1 7s. 2.65d. per ton. The expense amounted to £1 2s. 6.42d. per ton, leaving a net profit of £7808 3s. 7d. Milling operations for the first month showed an apparent loss of £2593 13s. 3d., due to the fact that a considerable amount of gold was absorbed by the plates and extractor boxes. The average duty of the stamps for the three months was nearly 8 tons. The ore reserves are estimated at 374,438 tons, having an average assay value of 7.48 dwt. Considerable enlargement of the plant is planned.

KNIGHT CENTRAL.

The Knight Central, Ltd., having acquired 450 claims of the South Knights, Ltd., now owns 895 claims on the Driefontein farm on the Rand, South Africa. In 1908 the capital stock was increased from £525,000 to £900,000, in order to provide for the purchase of the South Knights property. According to S. C. Thomson, consulting engineer, the ore reserves were increased from 282,100 tons having an average value of 7.75 dwt., to 395,400 tons valued at 7.7 dwt. In the west section of the property 1272 ft. of development, exclusive of shaft-sinking, was accomplished. In the east section the incline was sunk 729 ft., to the 13th level, and in addition 11,195 ft. of development and prospecting was done. In the early part of the year the work was disappointing, the ore found being of low grade. Later work, particularly in the South Reef, was more encouraging. A plant of 100 stamps and 3 tube-mills was erected and milling began on January 27, 1909. The addition of 20 stamps is planned.

WITWATERSRAND DEEP, LTD.

This company owns 425 claims and certain water-rights on the Driefontein and Klippoortje claims. It is under the management of Henry Hay, with S. C. Thomson consulting engineer. In 1908 the profit was £357,016 and the tons milled 442,420, as compared with £289,463 and 386,110 in 1907. The average profit was advanced to 16s. 1.67d., as against 14s. 11.93d., dividends of 55% being paid. This was possible, despite the lower grade of ore handled, through decrease in costs. These for December were 15s. 0.44d. The ore-reserves are stated to amount to 1,618,715 tons, having been increased to that from 601,915 in 1903. The present reserves are estimated at 7.79 dwt. per ton. In the stopes 17.35% of the ore was broken by machines at a cost of 5s. 7.15d., as compared with 6s. 4.86d. for hand-work. In all 177,018 oz. were recovered, 59.53% from the stamp mill and 34.47 by cyanidation. The stamp duty for the year was 5.25 tons. The cyanide extraction was 86.17 per cent.

Mine Signals in California.

In answer to a request from correspondents we re-print the California statute relating to mine signals. The only effect of the statute is to lay violators open to action for civil damages, in which the case would be determined by preponderance of evidence only.

Act 2225.—An act to establish a uniform system of mine bell signals, to be used in all mines operated in the State of California, and for the protection of miners. [Approved March 8, 1893. Stats. 1893, p. 82.]

Section 1. Every person, company, corporation, or individual operating any mine within the State of California—gold, silver, copper, lead, coal, or any other metal or substance where it is necessary to use signals by means of bell or otherwise for shafts, inclines, drifts, cross-cuts, tunnels, and underground workings—shall, after the passage of this bill, adopt, use, and put in force the following system or code of mine-bell signals, as follows:

- 1 bell, to hoist. (See rule 2.)
- 1 bell, to stop if in motion.
- 2 bells to lower. (See rule 2.)
- 3 bells, man to be hoisted; run slow. (See rule 2.)
- 4 bells, start pump, if not running, or stop pump if running.
- 1—3 bells, start or stop air compressor.
- 5 bells, send down tools. (See rule 4.)
- 6 bells, send down timbers. (See rule 4.)
- 7 bells, accident; move bucket or cage by verbal orders only.

- 1—4 bells, foreman wanted.
- 2—1—1 bells, done hoisting until called.
- 2—1—2 bells, done hoisting for the day.
- 2—2—2 bells, change buckets from ore to water, or vice versa.

3—2—1 bells, ready to shoot in the shaft. (See rule 3.)
Engineer's signal, that he is ready to hoist, is to raise the bucket or cage two feet and lower it again. (See rule 3.)

Levels shall be designated and inserted in notice herein-after mentioned. (See rule 5.)

Sec. 2. For the purpose of enforcing and properly understanding the above code of signals, the following rules are hereby established.

Rule 1. In giving signals make strokes on bell at regular intervals. The bar (—) must take the same time as for one stroke of the bell, and no more. If timber, tools, the foreman, bucket, or cage, are wanted to stop at any level in the mine, signal by number of strokes on the bell, the number of the level first before giving the signal for timber, tools, etc. Time between signals to be double bars (— —). Examples:

- 6— —5, would mean stop at sixth level with tools.
- 4— —1—1— —1, would mean stop at fourth level, man on, hoist.
- 2— —1—4, would mean stop at second level with foreman.

Rule 2. No person must get off or on the bucket or cage while the same is in motion. When men are to be hoisted, give the signal for men. Men *must* then get on bucket or cage, *then* give the signal to hoist. Bell cord must be in reach of man on the bucket or cage at stations.

Rule 3. After signal "Ready to shoot in shaft," engineer must give his signal when he is ready to hoist. Miners must then give the signal of "men to be hoisted," then "spit fuse," get into the bucket, and give the signal to hoist.

Rule 4. All timbers, tools, etc., "longer than the depth of the bucket," to be hoisted or lowered, must be securely lashed at the upper end to the cable. Miners must know they will ride up or down the shaft without catching on rocks or timbers, and be thrown out.

Rule 5. The foreman will see that one printed sheet of these signals and rules for each level and one for the engine-room are attached to a board not less than twelve inches wide by thirty-six inches long, and securely fasten the board up where signals can be easily read at the places above stated.

Rule 6. The above signals and rules must be obeyed

Any violation will be sufficient grounds for discharging the party or parties so doing. No person, company, corporation, or individuals operating any mine within the State of California shall be responsible for accidents that may happen to men disobeying the above rules and signals. Said notice and rules shall be signed by the person or superintendent having charge of the mine, who shall designate the name of the corporation or the owner of the mine.

Sec. 3. Any person or company failing to carry out any of the provisions of this act shall be responsible for all damages arising to or incurred by any person working in said mine during the time of such failure.

Sec. 4. This act shall take effect immediately.

A Novel Gravel Elevator.

The elevation of gravel in hydraulic mining has always been a serious problem. It has constituted a heavy expense, and the low gold-tenor of the average placer is such as to necessitate severe economy. The hydraulic elevator has been eminently successful when there was an abundance of cheap water available under high pressure. It replaced no other part of the operation; the hydraulic giant was needed for caving the bank and supplying the water to wash the material to the elevator pit, where a new jet of water could drive it up a pipe to a sluice; in short, the only function performed was that of gaining grade for subsequent sluicing in the ordinary way. Mechanical elevators have proved almost universally unsuccessful because of their small capacity and high cost of maintenance. The field for mechanical elevators seems to be limited except for machines of great size, constructed as ponderously as a dredge, and costing an almost equal sum. These disadvantages have led to the invention of a new system, known as the Ruble Gravel Elevator, which, in effect, consists of a combined grizzly and undercurrent, placed at the head of an inclined flume or box, up which the gravel is driven by a stream from an ordinary hydraulic giant. The spent water spreads out with the gravel over an apron leading to a grizzly, beneath which is the undercurrent. The latter is, in fact, a return sluice, fitted with riffles in the same manner as a sluice on a dredge. The apparatus is compactly built, and is mounted on wheels. It can be moved forward and backward near the face of the gravel, the tailing being stacked as it is moved. The gravel may be conveyed to the appliance by mechanical or hydraulic means. The Ruble elevator has been in use in Idaho, Oregon, and other States, with excellent results. It has solved a difficult problem in placer mining. The apparatus is manufactured by Ruble Bros., Golden, Oregon.

Commercial Paragraphs.

The ERNST WIENER CO., New York, has appointed W. K. Kenly Co., First National Bank building, Chicago, as its district sales agents.

The ALLIS-CHALMERS CO. has moved its Los Angeles office from the Citizens' National Bank Bdg. to larger and more convenient quarters at 129 East Fifth street.

The WOOD DRILL WORKS of Paterson, N. J., has put in a stock of drills at Toronto, Ontario, Canada, at the show rooms of the A. R. Williams Machinery Co., which has branch offices in Winnipeg, Vancouver, and Montreal.

The FRED M. PRESCOTT STEAM PUMP CO., Milwaukee, Wis., advises that in order to meet the increasing demand in the Southern and Southeastern States an office has been opened at the Candler Bdg., Atlanta, Ga. R. L. Radcliffe will be in charge.

Dividends.

On Tuesday, May 4, the Bunker Hill & Sullivan Mining & Concentrating Co. will pay dividend No. 140 of \$45,000. This makes the amount of dividends paid since January 1 \$300,000, and the total to date \$10,971,000.

EDITORIAL.

LATERAL EXPLORATION rather than additional sinking is often the wiser as well as cheaper form of development. The Camp Bird management, acting on the advice of Mr. J. E. Spurr, has been exploring the western end of the property, and Mr. W. J. Cox reports finding ore running over \$200 per ton.

SUPPRESSION OF REPORTS is a poor way of inspiring confidence. The stockholders of the Tennessee Copper Company are wondering why they fail to see the report of operations for 1908. It is understood that the report was printed, but has not been distributed. Since the property has been producing, no such secrecy has ever been observed.

EXTRA-TERRITORIAL rights are rapidly disappearing. The last to be surrendered were those of British subjects in central and southern Siam. Northern Siam has for a number of years had a system whereby the British Consul sits on the bench with Siamese officials. Such anomalies, and that of our own Federal court at Shanghai, are incidental to the contact between civilizations of differing ideals. They disappear as peoples come to better understanding.

SEATTLE is working hard to make the Alaska-Yukon-Pacific Exposition, not the largest but the most beautiful world's fair yet held. In this we hope it may succeed. Mere size in expositions is little to be commended, and we are glad to see emphasis in this case put on beauty, which the site on Lake Washington, with its mountainous background, renders particularly easy of realization. The exposition will probably be remembered also as the one ready on time. Remarkable progress has been made in erecting buildings and installing exhibits. There will be much to interest mining men, and even the 'Midway' is to be called the 'Pay Streak'.

PLACER-TESTING seems simple. In principle it is one of the simplest things on earth, but accuracy necessitates attention to details and an understanding of the means for overcoming constantly recurring difficulties, which knowledge cannot be learned through an inspirational process. The gross errors in sampling that have led to so many disastrous failures in dredging have been due to over-estimation of the gold-content in the gravel. The public has been persuaded that dredge-mining is the safest on earth, that the net profit from a given area can be absolutely calculated. The gross value certainly can be approximated almost as closely as the gross tonnage from a coal seam, if one knows how. The article on testing dredgeable gravels, by Mr. William H. Radford, printed in this issue, is a notable contribution to the subject. It explains the approved

modern practice, by one who has taken a leading part in developing it. He speaks with the authority of years of experience in which he has been able to compare the results of subsequent dredging with original estimates from sampling in many fields.

COMPARISONS, when carefully made, are extremely useful, and we think many of our readers will be interested in the paper on 'Methods of Copper Mining' appearing in this number. Mr. H. L. Hancock, the author, is general manager for the Wallaroo & Moonta Mining & Smelting Company, Limited, and his observations are based on a visit to the principal copper mines of Europe and America made in the interest of his company.

WHILE the Anaconda copper mine was closed the stock of the Amalgamated Copper Company touched a low level, and during the first two months of 1908 the quotations dropped to 45 $\frac{1}{8}$. The reaction has been steady ever since, until on May 8 the price had mounted to 84 $\frac{3}{4}$, a gain of 11 points in a month. This was in spite of the anticipated death of Mr. H. H. Rogers, and of the knowledge that the cost of shutting down had produced a deficit on the year's operation of \$1,317,020. This was covered out of the honey in the hive from previous flowery seasons. The surplus on hand at the end of 1908 was \$4,944,443, out of which dividends of \$2,400,000 were paid. The rally in prices can not be accounted for except as being an evidence of belief that the long-cherished purpose of the group of capitalists controlling the Amalgamated to effect a combination for dominating the copper market was on the point of attainment.

PANAMA has laid many fields under tribute to aid in building the great waterway. We referred in our issue of May 15 to the visit of Mr. Sidney B. Williamson, Chief of the Pacific Division of the Canal. We understand that the object of Mr. Williamson's visit was to study hydraulic mining methods in California, Oregon, and elsewhere, with a view to applying these to the excavation of a section of the Canal between Miraflores and Corozal. It is proposed to develop sufficient pressure-water by pumping from tide-waters on the Rio Grande, and to excavate a total of about 8,000,000 cubic yards, elevating by semi-portable, dredge-type, centrifugal pumps. Part of the material will be used for a dam on the west side of the Miraflores lock-site, and the rest to fill and reclaim the swamp-lands on either side of the actual canal. The advantages of this system will be that work can progress considerably in advance of the time necessary to get the dredges up to that point, and will save the cost, delay, and annoyance of towing the product out to sea. The capital outlay and current expenditure of this method of operation will probably compare favorably with any system of dredging. The records of this work will be of value to future large pump-slucing projects. The influence will thus react beneficially upon the mining industry, which is contributing this method to the great national work that is to link the coast-lines of the Atlantic and the Pacific.

Rand Milling Practice.

Heavy stamps have forced the tonnage of gold mills in the Transvaal to a point scarcely dreamed of a few years ago. For about ten years, stretching from 1890 to 1900, a sudden outburst of inventive fever in the United States expended its fury in high-weight stamps. The increase from the old standard 750 to the 900-pounder was mainly promoted by cheaper transportation; the change could be made without altering the lines of mortars adapted to the lighter stamps; but when 1200-pound stamps were tried in the old mortars the output suffered, and costs were not reduced. The inventor accordingly sought to evolve special mortars to meet a fancied 'problem'; anvil-blocks were introduced, adding another difficulty to the mill-man's trials in keeping a rigid battery; everything was done except to work out new mortar-patterns on the old model, adapted in details to the larger mass of pulp and to the altered wave-motion. The mill-superintendents in South Africa, with that spirit of conservatism which is so strong in the British people, have been working out this problem according to the true principle of evolution, that of gradual change. The weight of stamps has been progressively advanced as other details have been modified to suit. The result is that 9 tons of ore per stamp per diem is a common duty today on the Rand, obtained with 1600-pound stamps. In stamp-milling we have not kept pace with the South Africans, and in the light of their achievement we may pronounce nine-tenths of the American mills an anachronism. We have advanced the cyanide process faster than the engineers on the Rand, but they are coming down the home-stretch at a rapid pace. They have perceived the need and value of co-operation and exchange of ideas as we have not. Close physical association of a large number of enormous mines has been responsible for that. We will not allow that it came from a broader original view than our own, but they have adopted the policy of association, with a full consciousness of its virtue. The Mines Trials Committee, recently constituted, has been busy elaborating new processes and wrinkles, which are now being applied on a working scale. This permanent commission tests and improves the methods recommended by inventors, who, in the face of this systematic scheme for betterment of an industry, would probably prefer to be called designers. There hangs an odor of the intellectually unkempt in the hair of him who poses as an 'inventor'. We are discovering things by method, not by guess, in these days; the scientific drag-net of Burbank is what the modern world relies on, and that is what the Rand managers rely on. It is the way that is sure to win. We note with interest, in the letter from our Johannesburg correspondent, that the tendency to discard amalgamation is increasing. That has become the order of the day with the silver metallurgists in Mexico. We suspect that Mr. W. A. Caldecott has been responsible, directly or indirectly, for the innovation on the Rand. He had observed the all-slime method south of the Rio Grande that has made ten dollar ore workable even in remote situations in the Sierra Madre. Amalgamation also seems

destined to become enshrined among the interesting relics of metallurgy. The great mines are coming to the simpler method of fine-grinding, agitation with cyanide solution, and filtering. The conditions which render amalgamation preferable are comparatively rare. We understand that Mr. Caldecott will soon present a paper to the Institution of Mining and Metallurgy, dealing with the evolution of recent practice on the Rand. This will probably set new standards which will have world-wide vogue.

Siberian Placers.

In the last decade the world's stock of gold has increased one-half, and in the last quarter of a century it has doubled. Since the discovery of America the production, according to the Bureau of Statistics, has aggregated \$13,000,000,000 in value. The world's fund of gold money now amounts to \$7,000,000,000, and expanding industry still constantly calls for more of the yellow metal. Producing it is the problem of the mining engineer. To find it, all lands are prospected and re-prospected. Placers, because they give quick returns and yield gold free from the base metals and consequent complications of metallurgy and markets, were first to be attacked, and interest in them is recurrent.

The pan, the rocker, and the sluice have been the common implements of gold mining for generations. Hydraulic mining was a later development, and dredging is the most modern. Gold which could be won by simple means was as open to our predecessors as to us. Except as new methods or new machinery serve us better, we can count on scant returns from re-working their ground. The pioneers were no mean miners, within the limits set by their tools, and many a modern engineer has uncovered bedrock only to find it had been swept clean 'in the 70s' or in remoter periods. The early miners had, however, neither our experience nor our machinery. Hampered always by lack of transportation, and usually by high cost of food and supplies, much gold was necessarily left. In Alaska and the Yukon, to take a modern instance.

Among the most inviting fields open to American miners is Siberia. With the cumulative experience due to work in California and Alaska, the cordial relations existing between Russia and the United States, and the liberality of the Siberian mining laws, there is no reason why Americans should not take large part in the development of that country. Good unclaimed placer gravel occurs in Siberia, just as accessible to San Francisco and Seattle as a great deal of that now being prospected and mined in Alaska, or even in the States. Last summer promising placer ground was staked and tested within ten miles of the Okhotsk sea, and many of the short streams running down into that body of water, though not largely prospected, are known to carry gold. Near the mouth of the Amur, Mr. C. W. Purington is re-working old gravels which contain 40 cents per yard and over. Back from this, and stretching to the Ural Mountains, 4000 miles away, is a territory 1000 miles wide—an area larger than the whole of the United States—throughout which placers occur and have been worked.

Siberia is by no means an unknown country, though relatively unpopulated. Mr. Purington and others have given many interesting details regarding it, in the technical press of England and the United States. It is far from being a frozen land, and the difficulties of living and work there are not greater than are constantly overcome in many parts of our own country. Preliminary geological maps have been made and are readily available. The production of numerous streams is recorded, and detailed knowledge of many areas can be had. The most complete report is that of Reutofski, a geologist long in the Government service, who has summarized in a single volume and map much that is of interest. According to him, up to 1904 Siberian placers have yielded at least \$700,000,000, and the old mines, if re-worked under modern conditions, would yield two or more times as much. If the unexplored territory and the yield of quartz veins be taken into account, an output many times larger may be expected.

The Lena goldfields, as may be seen from the map, would be opened to modern industry by means of a short railway from Lake Baikal to the head-waters of one of the tributary streams. One creek in this district, the Nakatami, yielded, according to Reutofski, between 1865 and 1900, \$54,000,000 from gravels having an average tenor of \$10 per yard. On the Akakan, one of its tributaries, the pay-streak is reported to be 300 to 500 feet wide, and has been worked for three miles along the stream. The gravel is 3½ to 15 feet thick and carries an overburden of 60 to 280 feet. It is only partly frozen. The stream has old bench gravels as well as modern alluvium. From 1868 to 1900, \$26,000,000 was taken from it, some of the gravel being worth as much as \$30 per yard. The Dolgardine, also a tributary of the Nakatami, has a pay-streak 70 to 350 feet wide, that has been traced three miles. The gravel is 10 to 40 feet thick and the overburden 40 to 90 feet. From 1885 to 1900 this stream yielded \$9,000,000 from gravels running \$4 to \$13 per cubic yard. From Verni creek \$15,000,000 has been won in a length of one and three-quarter miles. On another stream, gravels 7 to 10 feet deep, carrying \$12 per yard, have been mined. An English company working in this district obtained an average of over \$8.50 per cubic yard, through three seasons' operations. On the Nygri, \$22,000,000 has been produced from gravels running \$4 per yard. The situation here is exceptional, in that water was available with 350 feet of fall, and hydraulic work was possible. In general, future work must be done largely with dredges.

Northern Siberia is a great plain stretching off to the Arctic Ocean. Reutofski states that it carries many old marine shore lines. The great northward-flowing rivers give access to much of it from the trans-Siberian railway, and short railway lines may be readily built, where necessary. Knowledge and capital are needed. Heavy pumps to drain the gravel, more complete utilization of such water-power as exists, steam shovels and dredges in the place of hand-work and carts, and steam thawing are all demanded to unlock the stream of treasure. They say 'gold is the Siberian bottom'. In cleaning it there seems to be room for many miners.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

JOHN B. HASTINGS is at New York.
STUART RAWLINGS is in San Francisco.
W. S. NOYES has returned from Oregon.
THOMAS H. LEGGETT is in San Francisco.
CHESTER A. THOMAS has reached Dawson.
H. KILBURN SCOTT has left for Nova Scotia.
W. A. SCOTT leaves Seattle for Ketchikan, May 21.
JOHN W. FINCH has returned to Denver, from New York.
E. J. FRANZ is in San Francisco, on his return to Plumas county.

THEO. F. VAN WAGENEN has returned to Zacatecas, from London.

HERBERT HAAS has gone to Salt Lake City, Utah, and Cleveland, Ohio.

CHARLES M. BECKER is at the Bonanza mines, in Saguache county, Colorado.

J. PARKE CHANNING has been in San Francisco, on his way to Phoenix, Arizona.

F. M. FIELD, metallurgical engineer for the Tonopah Extension Co., has gone from Ogden to Tonopah.

FRANKLIN R. CARPENTER, of Denver, is at the Boyer-Nevada Copper Co.'s mines, in Churchill county, Nevada.

C. H. WILDMAN, of Placerville, has gone to Canada, to take charge of gold mines in the Algoma district.

S. E. BRETHERTON is in Shasta county, on business connected with the Friday-Lowdon Copper Company.

E. E. HARVEY, general manager for the Porcupine Gold M. Co., is at the property, in Alaska, ready to direct the season's work.

LAWRENCE N. WAGNER has sold his engineering and assaying business, but will continue to make his headquarters at Nevada City.

GILMOUR E. BROWN, of Aqua, Santa Iquique, Chile, is going to Scotland for a holiday trip. He will examine mines near Coquimbo and Santiago on the way.

OSCAR A. KNOX, recently general manager for the Octave Mining Co., Octave, Arizona, has sailed from San Francisco for Sydney, on his way to Western Australia.

THE CLASS in mine surveying of the Mackay Mining School at Reno, Nevada, will go to Grass Valley, June 1, for three weeks work in the Murchie and other mines, followed by three weeks study of mining geology.

THE APPALACHIAN ENGINEERING ASSOCIATION met in Roanoke, Va., on Saturday, May 8. The following papers were read: 'Lead and Zinc Ores in Wythe and Pulaski Counties', by M. M. Caldwell; 'Organization and Engineering Difficulties of the Virginian Railway', by William N. Page; 'The Virginina Copper District', by Thomas L. Watson; 'Geologic Engineering Code of Ethics', by B. Halberstadt; 'Properties and Uses of Mineral Gypsum', by F. A. Wilder.

THE PASSENGER LIST of the *Corwin*, which sailed from Seattle for Nome, May 10, included reservations for the North American Dredging Co., Gold Beach Dredging Co., Thomas S. Darby, H. Leland, William West, Frank Shara, Earle Hunt, R. J. Healy, Fairhaven Water Co., Thomas Ross, Louis Lane, E. W. Johnson, A. H. Dunham, J. Henry Smith, F. A. Martin, J. F. McCulloch, C. McKay, David Fox, J. E. Johnson, L. B. Jarvis, J. M. Johnson, Gerald Hutton, N. Wilson, A. Adams, A. Boarstad, R. B. Woodson, Charles Elwood, F. N. Wood, M. M. Henry, J. W. Schaffer, J. B. Crawford, Patrick Heenay, Nick Sinagra, Harry Benson, D. McDonald, A. Johnson, T. Parsons, John Glasgo, J. P. Peterson, John Stratton, Charles Mitchell, John Spritzer, F. H. Sharp, E. C. Benson, R. G. Leslie, M. Lavelli, P. J. English, Jack Gale, W. Watson, Joe Pongee, L. Vanhebbler, W. L. Burger, E. Siegenthaler, J. C. McGrumpey, P. Siegenthaler, N. J. Burger, P. D. Lahart, M. Verner, Joseph Miller, C. Schmitz, Patrick McFadden, James Gallagher, Robert Kirby, MacNamara

General Mining News.

ALASKA.

A correspondent at Nome writes that this has been a very quiet winter on the Seward Peninsula. No new strikes of importance have been made on the tundra and there will not be as many drift mines at work next summer as there were last, but the large companies owning ditch systems will operate with full crews. The snowfall to date has not equalled that of last year, but there is still a good snow month to count on.

The Ellamar mine, on Prince William sound, is opened by a 600-ft. 3-compartment shaft, and has approximately 5000 ft. of lateral development on a zone of chalcopryite ore in a slate formation. The ore runs from 3 to 14% copper and 32% iron. The mine has been operated the greater part of the time for 10 years and has been a profitable shipper. During 1908 not much ore was shipped, but operations are in progress now and ore shipments are to be resumed later in the year. The equipment consists of a steam-hoist, air-compressor, and a 600-ft. belt-conveyor for delivering the ore from the bins at the mine to the bunkers at the wharf. F. M. Jordan and J. D. Meenach, of Seattle, are active in the management, with L. L. Middlekamp as superintendent at the mine.—The Dunton mine, near Hollis, on Prince of Wales island, has a contact vein between slate and eruptive rock, having gold-bearing ore that runs \$20 per ton. Development has reached 200 ft. depth. The property is managed by M. K. Rodgers, of Seattle, who has shipped in a small stamp-mill for work during the period of further development.

ARIZONA.

COCHISE COUNTY.

Thomas Bardon has issued the annual report of the Shattuck-Arizona Co. for 1908, in which is shown the advance made in development work. No ore has been mined during the period, but improvements have rendered possible a daily output 25% in excess over that of the year previous. There are now nearly four miles of drifts and cross-cuts between the sixth and ninth levels, and 800 tons per day can readily be mined when market conditions become favorable. It has been deemed inadvisable to build a smelter at present for the same reason, but plans for so doing have already been considered. Mining operations have been conducted under the superintendence of Joseph Walker.—At the Lowell shaft of the Copper Queen Mining Co. the drift on the 1200-ft. level has been finished, and now all the ore above that level is being hauled by electric motors to the Sacramento. Electric motors have now superseded mule-haulage in the Holbrook mine, and recently some pairs of 20-hp. motors have been electrically connected to single controllers whereby from 30 to 35 mine-cars can be hauled at a trip. Ore production at present is about 2500 tons per day, nearly all of which comes from the Sacramento shaft. Gerald Sherman is mine superintendent, and J. S. Taylor, James Finley, and Thomas Devine are the mine foremen.—Sulphide ore has been struck in the Black Prince mine, near Johnson, at a depth of 430 ft. The shaft has been sunk 6 ft. in material averaging 20% copper.

GLEA COUNTY.

Options upon the Saddle Mountain, London-Arizona, London Range, and Ball Copper company properties, at Christmas, have been secured by Edward B. Kurtz on behalf of the American Finance & Securities Co., of New York. The four groups concerned comprise 3000 acres of land, and are being examined by the American company's engineers, Louis S. Noble and A. H. Jones, of Denver. The Saddle Mountain Co. owns a smelter with a capacity of about 225 tons per day, but a new one will probably be built on a larger scale for use of the combined properties. Kurtz says that the Phoenix & Eastern railroad will be extended eight miles to reach the mines.

YAVAPAI COUNTY.

The Big Stick Gold Mining Co., operating in the Eureka district, has lately received a 35 hp. steam hoist, two com-

pressors, and some machine drills at the mine, which is 20 miles from Date creek on the Santa Fe, Phoenix & Prescott railway. The company's 20-stamp mill has just been put in operation, under the management of Thomas E. Campbell.

CALIFORNIA.

ELDORADO COUNTY.

The Mount Pleasant mine near Grizzly Flats is soon to be re-opened. This mine has produced about \$4,000,000.

INYO COUNTY.

The Standard Consolidated Mining Co. at Bodie has overhauled its mill and made several improvements to the plant. Arrangements are being made to increase the capacity of the cyanide plant to handle the ore being developed in the lower workings.—The first big strike this year in the Bodie district has just been made, and there is quite an excitement in consequence. Quartz specimens of high grade have been brought back by the discoverers, A. Belmont and E. Gray, who say that the location of the new find is 10 or 12 miles south of Bodie. They naturally do not wish to specify any more accurately.—The Casa Diablo mine, 20 miles north of Bishop, is working 40 men. Clarence Beale is superintendent.—The Gold Ledge Mining Co. has installed two 30-ton Huntington mills and 10 cyanide tanks. An 800-ft. aerial tarm will be built to connect the mine and mill.—Lessees at the Silver Bow mine southwest of Bishop have struck ore that will be shipped to the smelter at Keeler.

NEVADA COUNTY.

The mill-run at the Oustomah mine for six days yielded nearly 200 lb. of amalgam, which is about \$1400. The ore is being taken out on the 800-ft. level and the vein has every appearance of remaining strong and it is believed that another fine shoot is being developed.—The Union Lumber Co. has the contract to furnish the Black Bear Gold Mining Co. with 40,000 ft. of lumber, to be used in the construction of the 10-stamp mill which the company recently purchased and has on the ground ready for installation. The shaft is now 300 ft. under the croppings and will be sunk 200 ft. farther. J. H. English is superintendent.—The Washington Mining & Milling Co. expects to have 20 stamps dropping at the Giant King mine in June.—The new 10-stamp mill at the Golden Gate mine has been started. W. P. Martin is superintendent.—The Ocean Star mine at Ormonde, four miles above Washington, has been bonded by M. D. Cooley to E. C. Reed and F. U. Hubbell, of San Francisco, the latter having made their first payment on the property.

SAN BERNARDINO COUNTY.

(Special Correspondence).—A 5-ft. vein of gold-bearing ore, running from \$25 to \$60 per ton, has been cut in the shaft on the Black Warrior claim of the Gold Park Consolidated mines. It is expected to start shipping soon. The company controls 52 claims, which are being examined by an English syndicate with a view to its purchase. The consideration is said to be \$300,000. The property is thoroughly equipped with machinery and 30 men are employed.—The Stanford Mining & Reduction Co. is steadily operating the Gold Coin and Stanford mines, near Johannesburg, with good results. The shaft at the Gold Coin is down 350 ft., with about 3000 ft. of development. The Stanford shaft is 300 ft. deep. The vein is composed of silicious ore, over 2 ft. wide, and is worth from \$20 to \$60 per ton. Equipment consists of a 15-hp. hoist, 10-stamp mill, and a 30-ton cyanide plant.—The Atalia Mining Co. is maintaining steady shipments of tungsten ore to Germany by way of San Francisco. About four carloads per month of high grade ore is sent out. Twenty men are employed. San Francisco people are interested.—John L. Winney and Fred Ferris have closed a deal for the Ward mine at Seventeen Mile post. The consideration was \$18,000. Extensive developments are intended.—A 3-ft. vein of \$18 ore has been cut at a depth of 30 ft. on the Great Northern claim of the Twenty-Nine Palms Consolidated property. Driving and cross-cutting is under way.—A new district, 10 miles from Soda Lake station, on the Tonopah & Tidewater railway, is attracting attention. The outcrops show copper, gold, and silver minerals.

San Bernardino, May 15.

SAN LUIS OBISPO COUNTY.

E. E. Henderson, superintendent for the Palmer Oil Co., has purchased 340 acres of oil land for that company. The land includes the Blakeman tract, 100 acres, and 240 acres of the Wickenden ranch.

SHASTA COUNTY.

Frederick Lyon, former manager for the Mammoth Copper Co., has succeeded as managing director for that company, following the term of A. F. Holden, who, while relinquishing his directorship of that company, will remain as a heavy stockholder.—The tramway from the Balaklala mine to the smelter at Coram has been repaired and started again.—The Mountain Copper Co. has discontinued the roasting of ores at Keswick. Two Wright roasters have been calcining sulphide ores in preparation for shipment to Martinez.

SIERRA COUNTY.

Some rich ore has recently been found in the Rainbow mine near Alleghany, which L. P. Woodbury has under bond.—The Bonanza King has some high-grade ore that it expects to ship to Selby's. E. H. Wilson is the owner.—An electric-lighting plant, two-drill compressor, and two machine-drills are to be added to the equipment of the Snowden Hill mine above Camptonville.—The old Brush Creek quartz mine near the Mountain House, which is owned by the Brush Creek & Ante-Up Mining Co., is to be re-opened. L. A. Armstrong, who has been here for several months, will be in charge of the property.

TRINITY COUNTY.

The vein is exposed in four levels of the Phillips & Hensley mine. Some specimen rock is being taken from the lowest level.—Work for the season has commenced on the famous Rattlesnake mine in Trinity. This property is owned largely by Santa Cruz people, including Jacob Liebrand and Ed. Armstrong.—The 5-stamp mill at the Grizzly mine is to be remodelled.—A 2-ft. vein of good ore shows in the face of the drift at the Yellow Jacket.—A slide in the ditch of the Union Hill mine occurred Saturday, taking out eight boxes of the flume.—The La Grange has just placed a crew of 15 men at work repairing the flume on the ditch-line on the west side of Stuart's Fork.

COLORADO.

CLEAR CREEK COUNTY.

J. H. Robeson, of Denver, has been appointed general manager for the Dives-Pelican and Seven-Thirty Mining & Milling Co. A working fund of \$100,000 is to be provided and during the next month additional men will be employed. Robeson was the manager of this property for several years previous to 1904, during which time over \$2,000,000 was produced.—The Burleigh Mining & Milling Co., holding the Pelican mill under lease, is now running two 12-hour shifts, and producing from 30 to 40 tons of concentrate per week. The new installation of machinery is effecting a saving of 85%. Two aerial tramways are in operation, the capacity of each being 125 tons daily. It is estimated that there is enough material available to insure the continuous operation of the plant for three years. W. A. Hood is manager.—A rich strike was made this week at the Marshall-Russell adit, the portal of which is situated at Empire Station, four miles below Georgetown. At a distance of 3000 ft. from the portal the Neef vein was intersected, an 8-in. streak of smelting ore being encountered carrying between \$65 and \$70 per ton in silver and lead. The percentage of zinc is so small that no penalty will be imposed by the smelters.—J. L. Young, the manager of the Golden Glory adit on Saxon mountain, has enlarged his development operations, and has lately cut a 2-ft. vein of \$28 ore carrying gold and silver. He now has 25 tons of first-class ore ready for shipment that is worth \$85 per ton. The same company is operating the Drummond group of mines, where machine-drills are to be installed, run by electricity.—The richest strike ever made in the history of mining in West Argentina is reported from the King and Queen property, situated on McClellan mountain, where the owners, Davis & Maxwell, have found a 6-in. streak of ore that assays 1227 oz. silver

per ton. The ground has been opened for 15 ft., with the ore-shoot still in evidence.—The output from the Josephine mine on Kelso mountain has been more than doubled during the last two weeks, and as soon as the roads are in condition, the ore will be brought to the purchasers in Georgetown. The manager, John Sapp, has started a new adit at a lower level than the other, and will soon install a water-driven compressor, as his company owns valuable water-rights on West Clear creek.

The fiftieth anniversary of the discovery of gold in the Rocky Mountains by George A. Jackson in 1859 has been celebrated at Idaho Springs. The location where the discovery was made has been purchased by Lafayette Hanchett, of Salt Lake City, and presented to Idaho Springs as a park. A monument has been erected on the spot where the first nugget was found.

GILPIN COUNTY.

The Newhouse tunnel was driven 303 ft. in March and is advancing 10 ft. per day. It has cut veins in both Illinois and Gardner mines.—George T. Mosch, of Tolland, has taken a contract to extend the Gold Run cross-cut adit near the head of South Boulder creek, in which Hirsch & Co. of New York are interested. The main level is in a distance of 420 ft.—Jose & Co., leasing in the 400-ft. level of the Specie

Counties of Colorado.

Payment mine on Bellevue mountain shipped a lot of smelting ore to the Chamberlain sampling works.—The Eureka mine of the Gilpin-Eureka Mining Co. is shipping heavily to local stamp-mills.—The Senator and Senator Extension mines, situated east of Black Hawk, were recently purchased from the Black Hawk owners by the Senator Mines Co., and operations have been revived under the superintendency of Matt Ryan.

LAKE COUNTY.

The Ball Mountain adit at the head of California gulch has been connected with the old workings of the Sunday mine through a raise driven from the breast of the bore. The raise was driven almost perpendicularly from the adit level, and is 220 ft. high. It connects with an old drift in the Sunday some distance from the main shaft, but serves the purpose for which it was driven, that of drainage and ventilation.—Six furnaces are now running at the Arkansas Valley smelter. This is an increase over the number that were in operation there during the winter.

SAN JUAN COUNTY.

The Silverton smelter has been sold by the Ross Mining Co. to W. B. Lowe, of New York. The consideration named is \$60,000, of which \$6000 has been paid down. The Silverton smelter was erected in 1900 by the Kendrick-Gelder company and was operated by them on their own and custom ores until it passed into the hands of the Ross company in 1906. They operated it for two summers, and since that

time it has been idle. It is said that W. B. Lowe is also purchasing the property of the Arpad Mining Co., consisting of 23 claims on King Solomon mountain.—Benjamin Ross, of Silverton, has been in Denver purchasing machinery for a cyanide plant to be built on the Esmeralda property in Minnie gulch. From this property much good ore has in the past been shipped to the Durango smelter, and the remaining low-grade material is now to be treated by the cyanide process. Gold is the predominating metallic content.

TELLER COUNTY.

The Consolidated Tramway Co., of Roanoke, Virginia, has commenced the construction of the aerial tram, to extend from the Midget mine, on Gold hill, to the Gold Issue mill, on the northeastern slope of Carbonate hill. The distance to be traversed is about 10,800 ft., and will be built according to the Loop Section system, by which each section operates independent of the others.—The El Paso Consolidated Gold Mining Co.'s estate that last year produced \$243,000 under the leasing system has, with the exception of certain blocks reserved for operation on company account, been thrown open to lessees, and already 31 sets of lessees, employing about 150 miners, are at work. The royalties are graduated from 15% on low-grade milling ore to as high as 50% on the high grade. Output in April amounted to 2000 tons of an average value of \$27, and it is confidently expected that by the end of May production will be increased by adding to the number of lessees at work.—A new hoist has been installed at the main shaft of the Golden Cycle mine on Bull hill. When in working order the production will be materially increased, and should easily produce 400 tons per day if necessary.

IDAHO.

BLAINE COUNTY.

During the past three months the Nay Aug mines near Hailey have yielded between four and five 50-ton carloads per month, worth about \$20,000. This is enough to pay expenses. But now John Thomas, the superintendent, is going to increase the force of men at work, and will also let out several contracts for opening the 900-ft. level. Thomas is now employing 25 men.—D. S. McGonigal, of Custer, South Dakota, has secured an option on the South Fork mine, locally known as the Espey mine. It belongs to Alfred Adams, who bought it in 1907 and developed it by an adit which cut a rich vein when 400 ft. long. There is a 5-stamp mill on the property. The river near by furnishes enough power for all purposes.

BONNER COUNTY.

The Dixie Queen Copper Mining Co., of Sandpoint, has taken over the group of five claims in the Lakeview mining district and will develop the property. The company is capitalized for \$500,000, and will have William C. Ames, Charles Edwards, and Ignatz Weil for directors, with Andrew Christenson as manager.—James Ferguson, president of the Princess Panama Mining Co., on Blacktail mountain, announces that operations will shortly be resumed, as an engine, generator, electric motor, hoist, and pump have been installed. The company will add several machine-drills and electric lights. The mine is being worked by lessees who pay the cost of development and a 20% royalty on ore sent to the smelters.

SHOSHONE COUNTY.

F. W. Bradley, president of the Bunker Hill & Sullivan Mining & Concentrating Co., has stated that the mine is in better shape now than it has been at any time in the 20 years he has known it. Development work has brought more ore in sight than has ever been had before, and there is enough blocked out to maintain the present output of 20,000 tons per month for the next ten years. Much of the ore blocked out is low-grade, but the new 500-ton mill which will soon be finished will increase the mill capacity by nearly 50%. There are 500 men employed at the mine.

Fourteen feet of galena ore has been encountered on the 600-ft. level of the Corrigan property, three miles west of Wardner, owned by the Page Mining Co.—The H. E. M. Mining Co. is sacking ore from the upper workings where

a rich strike was recently made.—The Snowstorm Mining Co. paid \$45,000 dividends on May 2 at the rate of 3c. per share. This is the third dividend this year.

MICHIGAN.

Sinking has temporarily been stopped at the Ojibway mine, both shafts being bottomed just below the 800-ft. level. The cross-cut on that level is being advanced to reach the Kearsarge lode, which is only about 70 ft. distant.—The Michigan is opening exceedingly rich copper ground in the so-called North amygdaloid. The lode has been drifted upon for a distance of 183 ft., showing an average width of 12 ft., of which fully 8 ft. is evenly shot with copper. It is said to be as rich as the portion of the Kearsarge lode opened in the Ahmeek mine, from which 24 lb. of refined copper per ton of rock is being made. There are about 360 men at work in the mine under the superintendence of Samuel Brady.—The Winona Copper Co. is working actively in the No. 4 shaft, and has blocked out 1,500,000 tons ready for stoping. The plans for the new stamp-mill have been drawn and a site made ready for it midway between the Winona and King Philip mines. Construction is expected to begin within the next few months.—Captain Benjamin Chynoweth has just died at Laurium in his 78th year. He was one of the earliest pioneers in the copper country, coming from Pennsylvania in 1856, and for many years was actively connected with the National and Mass mining companies.

MISSOURI.

JASPER COUNTY.

To the west of Joplin there are several mills being erected in the disseminated blanket formation belt. The Briggles mill on the Luke and Ashland is practically completed. It is a 250-ton plant, and will treat the ore from two well-developed shafts. In the same vicinity the Big Fly mill has been brought from the Alba camp and re-erected on the Black Cat lease. The Kittie Mack is being thoroughly developed by an Ohio company and will later have a mill. There are two shafts sunk in a good disseminated ore deposit at 175 ft. that were previously discovered by drill-holes.—The eastern end of the county is seeing unusual activity, and some excellent strikes have been made. A drill-hole on the John Denney farm near Knights has run into ore at a depth of 225 ft., and continued in it for 40 ft. On the George Shelton farm, to the northeast of Carthage, drill-holes have exposed a 10-ft. blanket deposit; and a still larger one has been exposed on the Boyd and Carnahan land at Sarcoux.

MONTANA.

FLATHEAD COUNTY.

Peterson, Kraus & Turnvall have organized the Grey Eagle Mining Co. of Newport, Washington, with a capital stock of \$1,500,000. They own a group of claims in the Troy mining district on which considerable assessment work has been done during the last 12 months. These are copper-gold properties and will be worked extensively during the coming season.

MISSOULA COUNTY.

Announcement is made that the old Iron Mountain mine, near Superior, in the eastern part of the Coeur d'Alene, will resume operations, and it is figured that within the next six weeks not less than 150 men will be employed. Patrick McElmeel, of Mullan, is superintendent and is installing two boilers and a 15-drill compressor plant.—Galena and carbonate ore is being encountered in the face of the drift being run on the Cuba Mining Co.'s property in the Nine Mile district. The drift is in 630 ft., and has a depth at the face of 350 ft. A good showing of galena ore was made in the upper workings at a depth of 160 feet.

NEVADA.

ESMERALDA COUNTY.

Wallace Macgregor has been appointed manager for the Nevada-Goldfield Reduction Co., and will have entire charge of the operations of that corporation.—The water supply of Goldfield now reaches a total of 350,000 gal. each day, which is ample for all needs. The new pumping plant is

situated in the vicinity of Lida, near some new springs which the water company recently developed. The supply has been increased between 60 and 70 per cent.

NYE COUNTY.

(Special Correspondence).—The shaft at the Montgomery Shoshone is down 700 ft., but most of the work is going on at the 'glory hole', near the 200-ft. level. This hole is approximately 200 by 300 ft. in dimensions on the surface, and the ore is gathered on the 200-ft. level through chutes. The orebody runs about \$12 per ton. A Chilean mill and other machinery will be added to the mill within a few days. It is estimated that \$1,000,000 in ore is blocked out. John Kirchen is superintendent.—Denver lessees on Tramp Consolidated have opened up a vein varying from 12 to 24 in. wide. Assays show from \$30 to \$100 per ton. About four tons of \$200 ore will soon be shipped. The abandonment of work on company account was recently ordered from headquarters at Philadelphia.—The old shaft on the Goldsworthy lease on the Starlight has exposed the Mayflower vein. About 6 ft. of the ore runs \$12 per ton.—The Denver owners have resumed work on the Nevada-Bellehelen group. It is understood that arrangements have been completed for the installation of a mill and pipe-line. At the time work was suspended sufficient ore was developed to warrant the erection of a reduction plant.—A 7-ft. vein

obtained of about the same grade material. But the greater part has been taken from the 2300-ft. level, where the average ore assays \$37 per ton. The Ophir shipped 270 tons of second-class ore to the Kinkead mill, and a carload of concentrate to Selby's smelting works. The Consolidated Virginia, Mexican, Union, Sierra Nevada, and Andes mines have all been turning out small quantities of ore, but at the Gould & Curry, Savage, Chollar, Potosi, and Hale & Norcross mines no work has been done.

OREGON.

BAKER COUNTY.

Work at the Morning mine, near Greenhorn, is progressing well, and 30 tons per day are being produced by a force of 14 men. The Psyche mill has been purchased and will be moved to the Morning mine when the snow goes and the roads are in condition for teaming. The plant is a 20-stamp mill, and is one of the best equipped mills in the district.—The Eureka-Dei Gratia mines are situated 15 miles from the terminus of the Sumpter Valley railroad, and just east of the county boundary. They are owned by Ira Lemons and John Millard, who have driven two adits on the vein, one 300 ft. and the other 115 ft. long. The ore-shoot has been proved for a distance of 200 ft. by numerous open-cuts and short shafts, showing a vein from 4 to 8 ft. wide, averaging \$55 per ton. The property is approached by a good wagon-

General View of Virginia City, Nevada.

of good grade ore has been intersected on the 150-ft. level of the Round Mountain Sphinx property. M. J. Kiely is superintendent.

Rhyolite, May 15.

It is reported in Rhyolite that a deal is on foot to utilize the mill of the Homestake King mine for the treatment of the low-grade ores from the Pioneer lease.—The Gold Hills Mining Co., in which the controlling interest was sold a few days ago by W. J. and Richard F. Tobin to Wingfield and Brown, has brought suit against the Pioneer Leasing & Mining Co., and against the Bullfrog Pioneer Co., for \$250,000, alleging this to be the value of ore taken from within the lateral lines of the Gold Hills company's property. The suit is said to be of a friendly nature, to speedily settle the question of apex rights.

STORY COUNTY.

The litigation between conflicting stockholders in the Comstock Golden Gate Mining Co., operating on the Comstock lode, Virginia City, which has been pending several months, has been terminated, an amicable settlement having been made whereby the controlling interest has passed from San Francisco stockholders to stockholders in Oregon and Washington. M. J. Carrigan and C. Justice Kennedy represent the latter interest, and it is announced that operations at the mine will be resumed at once.

The weekly reports from the Comstock mines show that most of the repair work has been accomplished in the Sutro tunnel; timbers have been renewed, and both water and air pipes replaced where defective. From the 2100-ft. level of the Ophir mine 23 cars of \$22 ore have been extracted from the sill floor. From the 2200-ft. level 56 others cars were

road, and a water-right that controls 500 miners' inches at the lowest stage.—Theodore L. Lammers, president of the National Mining & Leasing Co., who leased the Cougar property near Baker City for 15 months and bonded it for \$250,000, announces that active work will begin in a short time.

UTAH.

BEAVER COUNTY.

A. D. Moffat, manager for the Majestic Mines Co., has reported to the main office that he is now in 60 ft. in the south drift and 57 ft. in the north drift on the 500-ft. level of the Harrington-Hickory property. He states that the ore now being taken out assays 62.3 oz. silver and 35.2% lead. The main shaft will be sunk an additional 200 feet.

WASHINGTON.

FERRY COUNTY.

One of the results of the leasing system in Republic camp is that less ore is broken in the mines, but the average values are higher than those of ore broken under the companies' direct management. About 130 men are now employed in the camp, whereas only one-tenth of that number was working a year ago.—The lessees of the south end of the Surprise claim, owned by the Pearl Consolidated Mining Co., have carefully guarded against publicity of what ore they were shipping. It is now known that they are shipping five carloads of ore per week, or about 150 tons of the average value of \$33.66 per ton. The pay-shoot has widened from 18 in. to 7 ft. and averages about 5 ft. in width. About 15 men are now working on the lease, which expires about August 1, by which time it is expected the

company will have received sufficient from royalties to pay all past and present expenses.—The new machinery for the San Poil mine has arrived and is being set up. A pole-line from the New Republic Co.'s power-plant is being constructed to supply the electric energy.

KITTITAS COUNTY.

The Washington Quicksilver Mining Co. has been organized at Ellensburg with these officers: president, G. W. Tusinger; vice-president, W. G. Eckler; treasurer, H. Stebbins; secretary, Alonzo Rouche, all of Tacoma, where head offices will be established. It is purposed to begin active work at once. The property is 30 miles from Cle Elum, in the mountains, and has produced cinnabar giving a rich yield of mercury.

OKANOGAN COUNTY.

The Double-Header Mining Co. claims to have two systems of veins in a granitic formation, and that they intersect each other. The veins are nearly vertical, having a quartz and calcite gangue carrying silver and gold. In certain of the veins, however, the gangue is quartz unaccompanied by calcite. The development amounts to about 400 ft. of work. Assays of samples show from 20 to 400 oz. silver per ton, and a little gold. It is announced that a mill is to be erected to treat the ore, to consist of a crusher, Huntington or Chilean mills, a tube-mill and cyaniding equipment, to have 75 tons daily capacity. The plans contemplate a hydro-electric plant for power purposes. The property is at Nespelem, 35 miles from Elmira, on the Washington Central railroad.

STEVENS COUNTY.

Conrad Wolfe, manager for the United Copper Mining Co., operating near Chewelah, announces that orders have been placed in Spokane for a hoist, 10-drill compressor, cage, and 6 mine cars, to be installed within the next 60 days.

CANADA.

BRITISH COLUMBIA.

A good showing is being made by the Yankee Girl mine in the Nelson district. It is a property that only a few months ago was considered an ordinary prospect, but at the present time has nearly a million dollars of 'probable' ore. A force of 25 men is at work in the mine, and the adit has been advanced 1500 ft. There are 10 carloads of ore valued at \$20 to \$60 per ton on the dump awaiting shipment to the railroad.—A strike of 25 ft. of copper ore is reported from the Ikeda mine, on Moresby island. This mine is owned by Japanese capitalists, who were among the first to operate on the island. The mine is proving up well and is exceeding expectations in the way the ore widens out with depth. Recent assays show the ore to carry 13% copper, \$3.50 silver, and \$8.50 gold. On the strength of the showing of these mines the Granby Consolidated has bought the Contact group at Tasso Harbor.—Preparations are being made by the Portland Canal Mining Co. to install an aerial tram 1½ miles long this summer. The company will also develop 500 electrical horse-power from its water-rights to be used in part to operate the 50-ton concentrator which is to be installed at once. There are about 20,000 tons of ore in the workings above the adit level, and it is estimated this will average \$15 per ton. It is a 'dry' ore and will concentrate without trouble.

J. D. Brass, representing the Golden Zone Mining Co., operating near Hedley, reports strikes of good ore in the Golden Zone and the Kingston Gold & Copper mines. The first named group consists of four claims, with a shaft 100 ft. deep in which is a vein 10 ft. wide. The surface cropings are traceable for 2000 ft., and several samples have been found rich in gold. A 5-stamp mill has been installed and arrangements have been made for five more.—According to information obtained in Seattle the Nickel Plate mine on the upper Similkameen is under option to parties connected with the United States Steel Corporation. The Marcus Daly estate is the principal owner of the Nickel Plate, M. K. Rodgers, of Seattle, owning 15% of the stock.

The Hidden Creek Copper Co. is opening a copper mine on Observatory Inlet, 80 miles north of Prince Rupert. The property is situated 8000 ft. from tide-water, on a moun-

tain that rises 1000 ft. above sea-level, and consists of a zone of copper ore 2000 ft. in length and 400 ft. wide. The ore is a sulphide, having an excess of iron, and carries an average of 5% copper with \$1 to \$3 per ton in gold and silver. The initial workings consist of open-cuts, adits, and drifts, amounting to 2000 ft. An 8 by 8-ft. adit, being driven 500 ft. below the other workings, is now 600 ft. in ore, showing practically the same conditions at this depth as those in the first workings. Operations have been in progress a year, and \$200,000 have been spent on the work and equipment. M. K. Rodgers, of Seattle, is general manager for the company, and states that a smelting plant may eventually be erected on the property.

ONTARIO.

The structural steel head-frame of the Temiskaming company over the new shaft is completed. It rests on a solid concrete foundation and is over 70 ft. high.—The Cobalt Central company recently shipped a car of concentrate to the smelter at Copper Cliff, whose value increased \$1860 between the time it left the mines and the time it had been smelted and weighed, as a result of the increase of 3c. in the market price of silver within that period. Shipments from the camp continue in large volume.

In the bottom of a 30-ft. winze sunk in the 300-ft. level of the Temiskaming mine, the No. 2 vein now shows a width of 3 ft. with silver through the entire width averaging 3000 oz. per ton.

MEXICO.

GUANAJUATO.

The gold content of the Guanajuato district ores are keeping that camp active though silver is still low. Much development work is being done in the Pinguico, Santa Rosa, and La Luz districts, particularly in the latter, as electric power can be obtained at very reasonable rates.—The San Cayetano Mines Co. is unwatering its properties in this neighborhood. A diamond-drill is to be installed at the Ruby silver mine to try to find another vein. F. H. Clark is manager.—At the Guanajuato Consolidated Mining & Milling Co.'s mill 100 stamps are dropping, and a recently installed filter-press is giving an increased output.—The Rapid Economy mill which has been erected for the Vignos company to treat the ore from the Tres Coronas mine is now being tested.

PUEBLA.

The water flowing through the Necaxa river is so reduced in volume, due to the unusual drought in the mountains between the Mexico valley and the State of Puebla, that there is now only sufficient to operate one of the six generators. In consequence it is necessary to burn a large amount of coal at the Mexico City power-plant. The water in the upper reservoir is exhausted, and sluicing by monitors for the construction of the new dam has had to be suspended. Work is being rushed on the Tenango river dam and tunnel, as this, when completed will turn an important watershed into the Necaxa river, and in a great measure solve the problem now confronting the company's engineers. R. F. Hayward is general manager for the company.

WEST AFRICA.

The Taquah Mining & Exploration Co. owns two mines in the Gold Coast Colony known as the Taquah and the Abosso, from which excellent dividends are being returned. The Taquah mine is working a banket reef very similar to those on the Rand. It dips at an angle of 35°, and has been developed to a depth of nearly 1000 ft. on the incline through a shaft 20 by 7 ft., with two skipways. In August 1907 a 50-stamp mill with a cyanide annex was started, and is running most satisfactorily on ore averaging 1 oz. per ton. The cost of labor is apparently low, being between 25c. and 36c. per day, but is actually high owing to its inefficiency, and is the main reason for the cost of production being about \$8.50 per ton. Power is supplied by three German-made gas-producer engines, which are highly efficient and economical, effecting a saving of about 50% over the steam-driven plant. The company is said to be controlled by Ochs Bros., of London, and the mines themselves are under the management of G. A. Stockfeld.

Special Correspondence.

JOHANNESBURG, TRANSVAAL.

Slope-Drills Underground.—Annual Reports and their Merits.—Simmer Deep Ore Reserves. — Milling Experiments. — Distinctive Colored Wrappers for Explosives.

The underground elimination trials of the stope-drill competition have not run as smoothly as the preceding ones on the surface. Serious complaints have been heard as to the quality of the steel supplied—possibly because suitable tempering for the different classes of machine has not been fully determined and special requirements have not been met. Certainly the variations between surface and underground performances have been remarkable in several instances. Speeds recorded by certain drills are tabulated below, time being in inches per minute:

	Surface, In.	Underground, In.
Siskol	4.34	(1) 0.99 (2) 1.16
Westphalia	4.21	(1) 0.99 (2) 1.39
Flottmann	4.01	(1) 1.16 (2) 1.09
Climax Imperial	3.52	(1) 2.17 (2) 2.04 (3) 1.60
Holgate	3.45	(1) 1.07 (2) 1.16
Holman, 2¾-in.	3.11	(1) 1.89 (2) 2.32 (3) 2.48
Murphy	2.92	(1) 1.81 (2) 1.76 (3) 1.89
New Century OO	2.87	(1) 1.57 (2) 1.71
Konomax	2.48	(1) 1.61 (2) 1.27 (3) 1.30

Although the indifferent results obtained underground may be variously explained, and are in part attributable to difficulties and defects for which remedies may be found, the comparatively bad work done by the first two machines is significant after their exceptional work on the granite blocks.

The majority of the annual company meetings held in respect of the operations for 1908 are now over, and it must be admitted that, for lucidity and fulness of speeches made and of reports supplied to shareholders, Rand gold-mining concerns can find few superiors in other parts of the world. But there are exceptions, and it is particularly regrettable that it should be necessary to charge even one of the strongest and technically most progressive groups with 'sins of omission'. To specify, it is deplorable to find that neither the chairman nor the engineers of the Simmer Deep, Ltd., provide detailed information as to ore reserves. The chairman in his speech remarked: "The ore reserves have been carefully checked, and at the end of the year the amount developed was estimated at 747,000 milling tons, of an average value of 6.1 dwt." After noting that certain blocks had been excluded on account of insufficient reef-exposures in the drifts, he added: "There is, of course, a considerable amount of lower-grade rock, part of which will eventually be worked at a profit." The reports do not even go so far as this. Yet the mere fact that £459,876 has been expended on development giving this result (exclusive of shaft-sinking), should enforce a full declaration of the amount of unpayable 'reef' also developed. A general reference to the 'considerable' tonnage of unpayable rock does not meet the case. These remarks are not made in a spirit of captious criticism, but only in the hope that the public expression of these views may suggest the advisability of remedying the defect. The world has often been told that the deep-level

developments of the Central Rand have lately proved the fallaciousness of the theory of general impoverishment in depth. The revival of popularity in Kaffir investments has been largely brought about by the better prospects of deep-level mining, based on the results obtained in the City Deep, in the lower levels of the Village Deep as compared with the upper in the Cinderella Deep, in the Brakpan, and in other deep mines. If, however, full particulars of these encouraging developments are published and only scanty information is provided with regard to the less satisfactory features of Rand expansion, there is danger of reviving the old feelings of distrust. Both good and bad news must always be forthcoming from a mining industry of such magnitude as that of the Transvaal, and the balance has recently been so heavily in the favor of the good, that neither the Consolidated Gold Fields nor any other group need fear ill consequences from frankly presenting to the public every aspect of their position.

It is satisfactory to find that so many of the new proposals made for the improvement or alteration of methods in or below the mill are now being tried on a working scale by the Mines Trials Committee, and will therefore be tested to the widest advantage. The new organization is certainly working with energy and pluck; although it must necessarily lead to cases of dissatisfaction, by refusing to invariably share the enthusiasm of inventors and to incur expenditure on experiments of little promise, the Committee has already instituted investigations of sufficient general importance to justify its formation. Reference has previously been made to the tentative introduction of a non-amalgamation direct-cyaniding process at the old Wemmer mill of the Village Main Reef company. Another innovation of interest has lately been the employment of a Holman pneumatic stamp at the New Kleinfontein. The results of the trial should soon be known, but a long run should be made under varying conditions before conclusions are drawn. The heavy stamp experiments of the Consolidated Gold Fields extended over several years, and those who are now erecting 1500 to 1600-lb. stamps must recognize their obligations to the pioneers. The development of the heavy stamp in Rand battery-practice has been fraught with many difficulties. I understand that Mr. Caldecott is preparing a paper covering the whole question for the Institution of Mining and Metallurgy.

A question of more than local importance has lately been under discussion with reference to the use of colored wrappers for explosives. At present all the gelatine and gelignite is done up in white wrappers. Mr. Brett suggested in the Journal of the Chemical, Metallurgical & Mining Society that they should be made red, which would be more readily distinguishable from the whitish broken ore and to some extent assist in the detection of loose cartridges, thereby minimizing danger. The unexploded cartridges from partly misfired holes are not likely to be often found with wrappers attached, but bits of colored paper detected by miners or natives would act as a warning. A good deal of gelatine now finds its way to the sorting tables where it is picked out. A colored wrapper might be of service here also. As a controversy, the question raised is too one-sided to be of interest. W. W. Mein, Harry Johns, C. B. Kingstone, and a number of other authorities whole-heartedly favor the proposal, and there is only one opponent in Stuart Martin, the recently appointed consulting engineer to Eckstein & Co. Mr. Martin says he does "not think it matters very much whether the wrappers are white or red. The point is to improve supervision and prevent loose cartridges getting mixed with the broken ore." This is a counsel of perfection which scarcely meets the case. Mr. Martin is new to the fields, or otherwise his voice would probably not be heard in opposition to the opinions of all local mining men. The mere fact that the tamping of cartridges made from old newspapers, etc., are white is almost sufficient reason for adopting some distinctive coloring. It is, of course, perfectly realized that the scheme would only occasionally result in the detection of loose explosive cartridges, which would have otherwise been passed over; but anything contributing appreciably to greater safety 'mat-

ters' decidedly. An improvement in supervision is always desirable, and is a factor in the reduction of accidents from any cause; but the possibility of attaining it must not check the efforts of those in control to look to the greater safety of employees, who may be the victims of the carelessness of others. Mr. Martin seems to say that if supervision be bad, employees in the mine deserve to be literally, as well as metaphorically, blown up. Even allowing that by the improved supervision loose cartridges more rarely get "mixed in with the broken ore," would it not still be advantageous to use colored wrappers, so that (apart from the question of safety) the carelessness requiring correction could be

Wemmer Mill, Johannesburg.

more readily detected? Now that the mining community has expressed itself so strongly in favor of distinctive wrappers, it only remains for the manufacturers to respond to the appeal. Mr. Cullen, manager of the Modderfontein works, has had difficulty in conceiving a suitable pigment for the purpose, but this obstacle will surely be overcome.

DAWSON, CANADA.

Cold Winter.—Preparations for Summer.—Yukon Gold.—Lewis River Dredging Co.—Canadian Klondike.—Quartz Prospects.—Strikes.—Quartz Creek —Sulphur Creek.

The past winter has been a record breaker; old timers all agree that never before have they seen such cold. Beginning with December 26, and running continuously until February 24, the average was 35° below zero. The lowest point, 72° below, was touched several times. It is hard for people farther south to fully grasp what such a continued stretch of cold weather means. It was exceptionally hard to stand, and all are glad that summer will soon be with us again. The winter has been particularly hard on all those who were obliged to do outdoor work, consequently the gold output may be expected to be lower than last year. The wood-cutters have had their share of hardship, and it is likely that they will not make much out of their contracts. Everyone, however, is cheerful and full of hope for the coming summer, which bids fair to be a busy one. No damage has been reported to any of the plants. All the dredges are in good shape, and crews are now at work clearing away the snow and ice, and overhauling machinery. The ditches, flumes, dams, and pipe-lines have all stood the winter well. The thawing plants of the Yukon Gold Co. and of the Lewis River Dredging Co. are ready to start. Enough wood has been delivered to thaw ground sufficient to keep the dredges at work until October. The Yukon Gold Co. has three thawing plants on Hunker creek, and two on Bonanza creek. These five plants will keep their seven boats busy.

Much progress has been made in thawing ground on a large scale in the past two years, and there is no doubt that future developments will bring this process to such perfection that capital need have no fear of frozen ground. The Yukon Gold Co.'s power plant on the Twelve-Mile river is being made ready for the first run of water, which is expected about the first week in May. During the past winter this plant has been enlarged one third. The machinery for

this purpose was freighted from White Horse to Dawson by the White Pass Co.'s freight stages, and was landed in Dawson in splendid order. From Dawson to the power plant the machinery was moved by the Yukon Gold Co.'s own teams. Much credit is due to the management of the White Pass Co., and also to Angus McDonald, superintendent of transportation of the Yukon Gold Co., for the manner in which this freight was delivered, especially in so cold a winter. The plant will now be able to deliver 2000 hp., which is all that this company will need. There are at present about 200 men employed by the Yukon Gold Co. in clearing away the snow and ice of winter, and in generally protecting their property from the usual dangers of the spring break-up.

The Canadian Klondike Co.'s dredge, at Bear creek, is being put in shape for the summer run. This property has been in charge of Harold Brown during the winter. He will continue in charge until Fred Rothschild comes in, at the opening of navigation. Edward Simpson, general manager for the Lewis River Dredging Co., is preparing his boat for work, and also thawing ground. A good start has been made. Messrs. Milvain and McLaren are busy on Walkers Fork preparing for work. They are thawing with steam this season, a suitable plant having been shipped to their property over the ice. The Bonanza Basin Gold Dredging Co.'s boat will be ready to start as soon as weather permits. This boat made a record last year, and J. A. White, dredge master, is doing all possible to make a better showing for this season. James Wortham, the resident manager for this company, arrived a few days ago looking particularly well after a winter on the Gulf of Mexico. George H. Coffee, superintendent of hydraulics for the Yukon Gold Co., has also arrived. He is now busy getting his department in shape for the first run of water. Otto R. Brenner, general manager for the French Hill Water & Mining Co., is getting his hydraulic plant in shape. French Hill is opposite No. 16 on Eldorado, the Klondike's banner claim. The particular enrichment found here was undoubtedly due to the talus from French Hill, which is one of the richest bench claims in the Klondike. The Detroit Yukon Mining Co., for which Mr. Bender is also manager, and whose property is known as the Williams Concession on Hunker creek, has a force of men at work, opening up bedrock cuts and extending them. The water for this property comes from the head of Hunker creek. The supply is 500 in. during the wet and 200 in. during the dry season.

Excitement is rife here over the possibility of successful quartz mining. This is premature and is likely to do more real harm than good. However, there are excellent prospects, and doubtless some of these will eventually become mines. To date there are two good prospects under development, one known as the Hartman group, and the other the Lone Star, owned by Dr. Catto. These are really good prospects and are what we are banking on for the future. It will not be long before enough development work will be done to in a measure demonstrate their value. If it is successful we can then invite inspection with some assurance.

The usual spring harvest of strikes in all parts of the Territory are being discussed, much interest being centred on a find on Hubert creek, a tributary of Forty-Mile river. Joe Barrette, one of our best judges of the possibilities of a new find, panned \$3 from four pans, and thinks well of the creek. Good reports are also coming from Glacier creek, where, last winter, pay was struck at an elevation considerably above the supposed limit. Glacier is one of the oldest creeks in the country, being worked before the strike was made on Bonanza creek. On the lower end of Dominion creek at Granville, several large dumps are being prepared for the spring wash-up. Camil Pissinault has about 6000 cu. yd. in his dump. Peterson Bros. and E. O. Lent have dumps equally large. These will undoubtedly turn out well. There are many smaller dumps in this locality equally rich. On Gold Run creek, Messrs. Davis and Howe, on claim No. 14, have fully 7500 cu. yd.; Henry Merles, on claim No. 13, and Messrs. Morris and McDonald have each approximately 6500 cu. yd. ready. There has been very little done on this creek during the past few years, though it has always been

rated as one of our best. There was perhaps more work on Quartz creek this winter than any year since 1903. This is due to the discovery last summer of a new pay-streak which during the winter has been heavily worked. There are more dumps in sight along this creek than any other in the district. Many of them are large. The returns will be large; possibly the largest resulting from winter work in the Klondike. The lower end of Sulphur creek has also been a busy spot this winter and those who have dumps expect a good wash-up. There is very little evidence of the ice melting in the Yukon up to date. In fact it looks as solid as it did any time this winter, the result being that the wise ones predict that it will go out much later than usual. The usual ice-moving pools are all opened up, but not many bets have so far been made. Everyone is anxious to see some action on the river before making his guess. These ice guessing contests are a time-honored custom. Men, women, and children all make bets.

NOME, ALASKA.

Litigation.—Third Beach.—Tundra Work.—Little Creek.—Dry Creek.—Nome River.—Dredging Through Ice.—Precipitation.

The 'long, dull, dreary winter' is a myth. This one has not been half long enough, and the weather is quite a welcome change after a succession of California winters. The last overland mail for the outside, which leaves here this week, finds us rushing almost as hard as we were last fall. T. M. Gibson has been mining on the Third Beach east of Nome river. W. B. Watts, connected with the management of the Wild Goose Co. from the beginning of its operations, is now in charge of the Northwestern Development Co.'s business on the Peninsula. This company controls several subsidiary companies, among which are the John J. Seson Co., the North Coast Lighterage Co., and the Seward Peninsula railway, besides mining property in the Kougarak district.

The suit of the Wild Goose Mining & Trading Co. against Ed. R. Dunn for trespassing on the Mabel claim on Ophir creek came up in January and absorbed attention for about three weeks. Fink's racing team was used in gathering witnesses, and in spite of a few blizzards and an average temperature of about 40 below, everyone enjoyed the excitement. The verdict went against Mr. Dunn, and damages to the amount of \$3600 were assessed. The only startling feature of the trial was the production, by one of Dunn's witnesses, of an old weather-beaten diary, in which, under date of July 1900 was an entry of some survey notes that, of course, established the position of the disputed corner at the exact spot to which Dunn moved it in 1907. That this old diary, containing these very survey notes (and no others) should have lain neglected for years, to be accidentally brought to light just before this suit came up for trial, was truly a remarkable coincidence, but strange to relate it seems to have failed to impress the jury. There is a deep-seated prejudice in this country against the moving of a stake for any reason, and the usual assumption is that it is done for some dishonest purpose.

Nome is quiet, compared with the last three winters. The lull following the cessation of operations on the Third Beach, which has now been worked in a straight almost unbroken line from Little creek on the west to the head of McDonald creek on the east, a distance of five miles, has resulted in a greatly decreased demand for labor. The miners owning 'tundra' claims of unknown value are now prospecting them, and others are taking leases upon ground that in the past has been considered too low grade to work. To date no new strikes have been made—that is, nothing new in the sense that the Third Beach was new—but all of the well-known areas of concentration on the tundra have been extended, and two or three entirely new ones, carrying fairly good gravel on bedrock, have been opened up. In a great many cases several men have banded together for the purpose of working ground under lease from the owners, and, owing to the personal interest of each man in the work, it is possible for them to make good wages on ground that the large companies, hiring all their labor, could not

work without loss. Most of these lessees, or laymen, are giving up 20 to 25% of the gross output to the owners of the ground, which makes the work profitable for everyone concerned. Regarding the value of the ground and the cost of working on this plan, it is difficult to obtain accurate information, but in frozen ground, under ordinary conditions, it may be said that 'three feet of 3c. dirt' is a good proposition. This means that samples taken over a height of 3 ft. show an average of 3c. per pan. Allowing five pans per cubic foot this ground is worth 45c. per square foot of bedrock, or \$4.05 per cubic yard for the 3 ft. of pay-dirt.

The most active portion of the tundra lies between Dry creek on the east and a line from the mouth of Anvil creek to the mouth of Center creek on the west. Within these limits are included the Bessie, the Portland, and others almost as famous, the richest claims of the Third Beach. On several of these claims work is now being done on what is called the 'sloughover.' This streak parallels the Third Beach throughout, at a distance of about one hundred yards to the south. No rich ground has been found on it, but wherever the Third Beach was rich the 'sloughover' can usually be worked at a profit. The concentration of gold in this streak is apparently due to the formation of a bar similar in all respects to the bar that parallels the present beach outside of the surf line. On Little creek, the western limit of activity, the Pioneer Mining Co. is carrying on the most extensive operations of the entire district. Pay is being hoisted from 12 or 14 shafts by means of self-dumpers. About 175 men are employed.

North of the Third Beach line work is going on in the bed of Dry creek, and on the hillside on the right, ground of good value which is being prospected and blocked out with a view to working on a larger scale during the summer has been found at two places. Between the Third Beach line and the present beach, a distance of $3\frac{1}{2}$ miles, actual mining is largely confined to a belt several hundred feet wide running from the mouth of Anvil creek almost due south to a point half a mile west of the mouth of Snake river. This belt includes practically all of the producing areas on the tundra south of the 'sloughover'; the most important ones are the Monroeville Streak, the Intermediate Beach, and the Submarine Beach. None of these streaks extends far either to the east or west of the belt mentioned. Between Bourbon and Center creeks, a mile to a mile and a half back from the beach, two entirely new pay-streaks have been found this winter, but their extent has yet to be determined. Values as high as 'five feet of eight-cent dirt' have been reported. This corresponds to about \$2 per square foot, or \$10.80 per cubic yard. The left limit of Center for half a mile above its mouth is dotted with dumps, and while nothing rich has been found, most of the ground will yield good wages to the laymen, who are doing nearly all of the work. East of the belt referred to, across the portion of the tundra drained by Bourbon and Dry creeks, some prospecting is being done, but no ground has been opened up which could be drifted at a profit. Still farther east, beyond Otter creek, a new streak has been found about half a mile south of the Third Beach line. Five feet of pay on bedrock is said to carry from 3 to 5c. to the pan—75c. to \$1.25 to the square foot, or \$4.05 to \$6.75 per cubic yard. East of Nome river, on the Third Beach line, the Yellowstone claim is producing some of the best pay found this winter. One piece of ground extending about 400 ft. along the Beach line is said to carry an average value of \$3 or \$4 per square foot. The ground is frozen and the cost of working will not exceed 75c. per square foot. Several other operators are obtaining fair results in the same locality.

T. J. Lovett is installing an air-lift dredge, an invention of his own, on the ice of Bering Sea, a short distance west of town and several hundred feet out from the beach. He has done considerable prospecting work and claims that the gold is there and that his machine will recover it economically. It is said that the Nome Mining Co. will repair the Bourbon Creek dredge, which was started last summer, but which handled little or no gravel, owing to a series of accidents. The Wonder Creek dredge, situated about two

miles north from the Bourbon machine, was nearly completed last summer and is expected to commence operations early in the coming season. Upon the divide between Dexter and Anvil creeks, where some remarkably rich ground was worked by drifted mines in early years, several laymen are searching for pillars left in the old workings with moderate success.

A good supply of water is predicted for the coming summer. The snowfall came early, preventing the penetration of the frost to the usual depth, which means that surface workings can be quickly and easily opened up in the spring, and that the ditches will give less trouble than usual. Between the first of October and the first of March this winter the precipitation, reduced to inches of rain, was about 60% more than for the corresponding period last winter. It is not possible to even approximate the winter's output at this time. In some places all of the available pay will have been taken out before spring, and the dump will be sluiced with snow-water during the thaw; but where the extent and richness of the ground justify it, the winter's work is being confined to blocking out pay which will be hoisted and sluiced during the summer. The prospecting work for quartz that was carried on during the winter on Newton gulch, with a Keystone drill, has been abandoned on account of litigation over the property.

GOLDFIELD, NEVADA.

Consolidated Output.—Combination Development.—Nevada Empress.

In April the Consolidated Mines produced 19,480 tons, with an estimated net recovery of \$820,100; total costs of production amounting to \$119,500, and the net profit \$700,600. The heavier production in March was largely due to shipments of high-grade ore from the Hampton stope and of accumulated concentrate. March production was larger than for any previous month, and is not expected to be equaled regularly. During that month the mill-heads were undesirably high. Costs of production have been reduced to \$5.853 per ton, divided as follows: mining \$2.69, development \$0.74—these items including general expense—transportation \$0.103, milling, average for both mills, \$2.32. The cost of reduction at the new mill was but \$2,005 per ton. Over 1500 ft. of new development was completed in March, and the low cost demonstrates the high efficiency of the mechanical equipment and operating force. The mill can now treat at a profit ores as low as \$7 per ton. In the Combination mine development has been chiefly confined to the Hampton stope. The vein is opened at levels 4, 5, and 6, and by means of an intermediate cross-cut, midway between the 5 and 6. A raise has connected levels 5 and 6, showing the ore to be continuous. The high-grade seam, from 4 to 6 ft. wide, was exposed 30 ft. below the 280-ft. level. Stopes on levels 4 and 5 are opened 50 ft. The production from this vein in March was 3054 tons, containing \$667,347. These stopes have produced over \$900,000 to date. Boy claim, the rich ore-shoot now being opened up is appar vein, is now being explored at three levels.

The cross-cut at the 600-ft. level in the Mohawk mine has been connected with the Clermont shaft on the Jumbo. The stope at the 600-ft. level, in the southeast portion of the Mohawk, has been further opened up, exposing a large tonnage of medium-grade ore, together with a shoot of high-grade. Above this an intermediate drift from the main winze is in good ore. The body increases in width to the north. A large and even production is being made from the recently developed 260-ft. level of the Red Top mine, the stopes being almost continuous for 300 ft. On the Lucky Boy claim, the rich ore-shoot now being opened up is apparently not continuous with the large stope. It is extensively faulted, but is opened for a distance of 100 ft. and contains 10 ft. of ore that averages \$50 per ton. Good assays are being secured in an intermediate cross-cut above the 260-ft. level, to the west of the north drift; a discovery of importance, since this portion of the Red Top mine has heretofore been unproductive. On the Jumbo, work has been started from the Clermont shaft, and a high-power hoisting plant, designed to run by steam or electricity, has been in

stalled, together with a 200-hp. air-compressor and drills, ore and waste bins of large capacity, and special skips.

Lessees on the Consolidated are developing a large area of virgin ground, work in March amounting to 1658 ft., and royalties in that month being \$2664.45. Defects in the mill have been remedied and the entire plant is now running smoothly.

The Nevada Empress mine, in the Gold Mountain district, southwest of Goldfield, is proving successful, and its mill is satisfactory. The mine is opened by tunnels, the lowest of which is in 460 ft., and which at 700 ft. will give 700 ft. of stopping backs. Two winzes in an upper tunnel have developed 2000 tons of ore, and throughout the mine the ore carries an average of \$25 per ton gold. The main vein is large and has been opened at the surface for 4000 ft. The mill is of the Hathaway gyratory type, with a miller weighing 10 tons.

The capacity of the Florence Goldfield mill will shortly be increased 50% by the addition of a tube-mill and concentrating tables. T. G. Lockhart is now in Denver, conferring with A. D. Parker and other directors. The additional machinery will be ordered at once. The physical condition of the Florence mine is excellent. Combination Fraction officials predict a May production from that mine of over \$80,000. The leased Nevada Goldfield mill is treating 80 to 85 tons daily of ore averaging \$38 per ton, from the Fraction. The Daisy maintains an output of 75 tons weekly, and is developing at the 400 and 500-ft. levels. Driving at the new 400-ft. level in the Velvet workings of the C. O. D. Consolidated is in ore and affords 300 ft. of backs in the rich vein from which ore was taken at the 300-ft. level.

SALT LAKE, UTAH.

John D. Ryan in Utah. — Murray Smelter Closed. — Ernest Stenger on Utah Copper Staff.—Copper Product for April.

John D. Ryan visited Salt Lake recently. He inspected the International smelting site in Pine canyon. The railroad spur from the main line of the Salt Lake route to the smelter will be completed within 10 days. Mr. Ryan announced that the initial capacity of the plant would be 2000 tons and that additions would be made from time to time to treat every character of ore placed on the market. M. S. Dean, traffic manager of the Anaconda smelter, has been appointed to a similar position with the International. The old smelter plant of the Utah Consolidated is being dismantled and a portion of the material is to be used in the new furnaces.

A strike at the Murray smelter has resulted in the closing down of the eight lead furnaces. The smelting company has shown no disposition to accede to the demand of the men for an increase in the wage scale from \$1.75 to \$2.25 per day. One of the big officials of the smelter says that it would be to the advantage of the institution to keep the plant closed for several months, as it is receiving only enough ore to keep five of the eight furnaces in commission, and with the improvement in metal prices shipments will increase. In the meantime a large tonnage will accumulate so that the company can place all the furnaces in commission as soon as they are again blown in. The recovery from the Murray furnaces is only 90% lead, while that at the Garfield copper plant is 95%. This condition is very unsatisfactory to the company, and it is reported that the entire Murray smelter may be overhauled.

D. C. Jackling, general manager of the Utah Copper and of the Ray Con. Mining Co., has just returned from New York after an absence of two weeks. He announces the appointment of Ernest Stenger, formerly general superintendent of the Rio Grande railroad, to the position of field engineer for the two companies. Mr. Stenger will supervise the completion of the ore line at Bingham for the Utah Copper, and the line from Kelvin, Arizona, to the Ray properties. Mr. Jackling says April was a record-breaking month for Utah Copper, it having produced over 5,000,000 lb. of copper. The Ray mill will be ready for work within 18 months. The copper output from all of the mines of Utah during April was 10,000,000 pounds.

BUTTE, MONTANA.**Diamond C. & C. Decision. — North Butte. — Sandstorm Dividend.**

The Amalgamated Copper Co. has been unusually successful in the courts lately. The biggest victory was won in the celebrated smoke decision. That was followed by another in an injunction suit occasioned by debris and tailing from mines and smelters. Finally the Federal Court in Wyoming confirms the title of the Diamond Coal & Coke Co. to 2500 acres of coal land which the Government claims had been obtained by the company through fraud. The Diamond Coal Co. is a subsidiary concern of the Amalgamated company. The Government had brought a number of suits to set aside patents on the ground that the entymen acted in collusion with the company and that the lands were not subject to entry, as they were known to contain coal deposits. The defendant company not only denied the charge of fraud, but also denied that the lands were coal lands, and seems to have proved it. Judge Lewis finds that no coal was known to exist in the ground at the time patents were issued, and that no mining was done on the ground, though coal was mined on adjoining ground up to the boundaries of the defendant's lands. The Court finds that at the time the lands were entered they were grazing lands.

The lower levels of the North Butte mine are gradually improving, both the drifts on the 2000 and 2200-ft. levels having passed through the fault, where the ore was of a low grade. The Butte & Superior Co. has resumed sinking on the Blackrock shaft, which is down 1040 ft. It will be put at least 200 ft. deeper. A level has been opened at 1400 ft. and a good body of copper and zinc ore opened to the west. The copper assays 6% and the zinc 25. The orebody will be developed, but no mining will be done on it until the shaft is deeper and another level is opened. In the meanwhile, however, some zinc ore is being shipped from the 1200-ft. and other levels, and is being treated at the Clark concentrator. The Snowstorm Mining Co. paid another dividend of 3c. per share in May.

MIAMI, ARIZONA.**Miami Development. — Black Warrior — Cordova Mine. — Inspiration. — General Development.**

The Miami Copper property has stopped most of its exploratory work underground, and is cutting the orebody into 50-ft. blocks preparatory to extraction. The new 16 by 18-ft. six-compartment extraction shaft is now 350 ft. deep, and connected with the 420-ft. level of the working shaft. No further work will be done for some time at the Red Springs or Pascoe shaft, as the ground will be explored by a north-east drift from the Miami. The excavation for the new \$1,000,000 concentrator is well advanced. A steam-shovel is at work, and a large gang of workmen. As the Southern Pacific railroad grade has been finished to the junction at Bloody Tanks west of Pivot creek, grading will be rapid up the level 'wash'. The road will be operating in two months.

The Black Warrior is still shipping to the Old Dominion smelter, and developing the vein in depth on the 350-ft. level, at the same time running north to connect with the ore opened to the west at the surface, 900 ft. from any underground work. The vein does not outcrop in that distance, being capped by a dacite lava, although the vein proper is in dacite tuff and in a fault breccia of schist and diabase fragment. The Cordova company has built a wagon-road up Captain gulch and has leveled off a site for its new shaft, only a few hundred feet from the Miami development shaft. Work will begin this week, and it is confidently expected that the Miami orebody will be cut at a moderate depth. The new owners of the Inspiration company have done rapid development in the few months they have had the property. They have a shaft on the Joe Burk claim, near the Miami property, that is in a mass of schist, capping granite. The shaft is now 145 ft. deep and shows much high-grade 'glance' ore, with disseminated ore averaging perhaps 3½%. The second shaft, now 185 ft. deep, on the Bull Dog claim and near the breast of the old Worson tunnel, shows only low-grade schist ore, too lean for profit.

The shaft is on the east side of a by-fault, and cross-cutting should develop ore in depth. The company has built a new boarding-house and four large cottages in the gulch on the north side of the property. They have built a mile of new wagon-road, and girdled the slopes of the Miami belt. Two Star drills are at work and one hole is already over 300 ft. deep. The Keystone property is still being developed, but no information is given out. The new shaft near the east end of the property shows good chalcopryite ore, and is now 265 ft. deep. The Last Chance tunnel is being driven by contract and is now several hundred feet long. The dump shows glance ore, but no information could be had as to its position and amount. The two churn-drills are still working, one on the very summit of the mountain ridge, the other near the shaft, where a hole 700 ft. deep is practically completed. The Lewisohn mining geologist, W. H. Weed, was seen on the property but refused to discuss it.

GUADALAJARA, MEXICO.**Guanajuato-Jalisco Development Co. — Virginia & Mexico Plant. — New Copper Smelter. — Deseada Mine.**

Dwight Furness, of Guanajuato, one of the most widely known American mining men in Mexico, who has been operating in Guanajuato and Jalisco for a number of years, has launched the Guanajuato-Jalisco Development Co. to take over and further equip and develop six of the Furness properties. James C. Hinchliffe, a brewer of Paterson, N. J., is president of the company, and Mr. Furness is the general manager in Mexico. The properties are the Agua Blanca and Calabasa in Jalisco, and the Dolores, Cabres-tante, San Gregorio, and Sevillana in the State of Guanajuato, and they are held to represent \$500,000 in development work and \$350,000 in machinery and mill equipment. The stock of the new company is divided into \$1,000,000 preferred and \$3,000,000 common, and it is stated that enough subscriptions have been received to insure the carrying out of the company's plans. Work is to be resumed at once in the Agua Blanca mine, and the property is to be given a new power-plant and additional pumps. The Agua Blanca has a concentrating plant of 100 tons capacity. A contract for electric-power for the Dolores mine and 40-ton reduction plant has been made, and operations will be soon in progress at that property. Later the company will turn its attention and funds to the other mines. The formation of a subsidiary company for each of the six properties, when profitable production is assured, enters into the plans of the Furness concern. The big reduction plant of the Virginia & Mexico Mine & Smelter Corporation, in the Hostotipaquillo district of Jalisco, is nearing completion, and mill-operations are expected to start in June. In the beginning 150 tons of ore will be handled daily. The company owns the Cabrera, a famous *antigua*, and the Peralta and America mines, and has now a big tonnage of ore ready for the mill. W. J. Payne, of Richmond, Virginia, is president of the company, and Jesse Scobey is general manager. The reduction plant consists of stamps, tube-mills, concentrators, and a cyanide annex. It is the first of modern construction in the Hostotipaquillo district. The Copper Range Mining Co. of Chicago, C. D. DuBois general manager, has equipment for a 50-ton smelter at the Pacific port of Chamela, and will soon move it to the properties in the municipality of Purificación, Autlán, district of Jalisco. To facilitate the movement of the machinery a wagon-road is now being built from Chamela to the mines. Development has been in progress for some time, and the company will be ready for smelting operations soon. A. J. Vick, a capitalist of San Antonio, Texas, has started to re-open the old Deseada mine in the Hostotipaquillo district. A tunnel that will give a depth of several hundred feet below the old workings will be driven, and as soon as ore supplies justify it a modern reduction-plant will be erected. A deal for the Deseada and for a half interest in the adjoining San José mine and its extensions was made several months ago. Poles for the transmission line that will carry electric power from Guadalajara to the Etzatlán and Hostotipaquillo mining districts are being distributed.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Drying coal adds to its efficiency. The contained moisture must be evaporated, and it requires 1 lb. of coal carrying 13,748 B.T.U. to evaporate 6 lb. of water.

Wood usually decreases in bulk as seasoning goes on. A hundred cords green will make from 89 to 93 cords when dry. This is a factor of no small importance to dealers who handle large quantities.

Gold stealing from reduction works has been made the subject of legislative action in the Transvaal. Among the regulations to reduce the evil is the requirement that all amalgamating plates and zinc-boxes shall be kept covered with screens securely locked.

Copper-pitch ore is a dark brown to black substance with a glassy to resinous lustre, giving a dark brown streak and having a hardness of 4. It is a homogeneous mineral of indefinite composition, containing cupric oxide, silica, carbonic acid, and oxides of other metals, as zinc, iron, and manganese, with alumina and phosphoric acid. It occurs among the products of oxidation of copper deposits in limestone. A typical locality in America is at Morenci, Arizona.

Telford road is a name applied to a method of constructing durable highways devised by Thomas Telford, a noted Scotch engineer, toward the end of the eighteenth century. The system consists in clearing the surface to secure an even bottom, upon which are closely packed by hand blocks of stone as nearly cubical as possible, about 6 in. square. The interspaces are packed with smaller stones. On top of this foundation is spread broken stone, flint being best, to a thickness of 7 or 8 in. at the centre, thinning to 4 in. on the sides. This is compacted by rolling.

Macadam is a type of road which differs from the Telford in being built up of crushed rock, unsupported by the costly foundation of hand-laid blocks. It is less durable, but admits of easy repair. It was designed by John Loudon Macadam, also a Scotchman, and a contemporary of Telford. The tendency in recent years has been to use coarser material for surfacing the roadway, as larger pieces will approximate the crushing strength of the original rock, while small pieces will reduce to powder under pressures of 500 lb. or less.

Soap is the best material that can be employed for dressing amalgamating plates. It readily emulsifies and removes the grease and oils which get into the ore from the exhaust of air-drills, from car-axes, and from the machinery used in crushing. Animal fats are employed to an insignificant extent for modern lubrication, mineral oils having taken their place. These are not affected by soda or potash lye, the utility of which is restricted to saponifying fats. Any common laundry soap gives good results in cleaning

plates, but borax soap has been used in many mills with great success.

Tin ores in Bolivia are distributed in an approximately uniform course, extending from near La Paz southeastwardly to Choroloque. The tin occurs mostly in altered andesite, but some veins are associated with trachyte. The former yield the purer mineral. The veins in trachyte and slate contain antimony, copper, zinc, bismuth, and tungsten. The leading tin-producing district is at Oruro, the veins in the mountain of Huanuni being mostly notable. The Huanuni Co. is operating a vein from 2 to 8 ft. wide, from which a great deal of shipping ore containing from 20 to 50% of the oxide is sorted; the rest is crushed and concentrated.

Eight-hour legislation in California is supposed by able lawyers not to apply to foremen. The foreman's duty does not expose him as continuously to dust, fume, or gases as does that of the laborer. The foreman has duties which take him to various places, and usually require time spent in the office, making records and preparing reports. The new law, it must be remembered, is merely a police regulation, intended to protect workmen from undue length of exposure to supposedly unhealthful conditions. It is by no means certain that the California statute will be construed as applying to stamp-mills and works of similar character.

Adsorption is a phenomenon occurring under certain conditions when a salt in solution is taken up and held by colloids in a manner analogous to true solution in water. A highly concentrated solution, by reason of the intensity of the osmotic pressure, increases the adsorption effect. Van Bemmelen, however, maintains that a weak chemical combination takes place between colloids and electrolytes. The adsorption continues until an equilibrium is established between the concentration of the solution and of the colloid. Hence it has been held that the adsorption is in general an exponential function of the concentration. Metallic hydroxides are readily taken up in this manner by colloids.

Fuel required to thaw gravel may be estimated on the following assumptions: That a cubic yard of gravel in place contains 3000 lb. of solids with a coefficient of thermal capacity of 0.2, and 387.5 lb. of ice with an average coefficient of thermal capacity of 0.75; that the temperature is raised 50° F.; that a pound of coal contains 13,000 B.T.U.; that the boiler efficiency is 50%; that 75% of the heat leaving boiler is absorbed by the ground. Then heat absorbed per pound of coal equals 4875 B.T.U.; heat required to raise 3000 lb. gravel 50° equals 30,000 B.T.U.; heat required to raise 387.5 lb. ice 50° equals 14,531 B.T.U.; total heat required per yard of gravel equals 44,531 B.T.U. Pounds of coal per yard, 9,134.5; cubic yards gravel per ton of coal, 218.8. Then, roughly, 8 tons of coal per foot of depth per acre are required to thaw the gravel. Roughly, the heat required to thaw 'muck' is as 3 is to 2 compared with gravel; thus, 12 tons of coal are needed per foot deep of 'muck' per acre.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Short Zinc.

The Editor:

Sir—In the discussion on short zinc which has appeared in recent issues of the MINING AND SCIENTIFIC PRESS, one cause of the trouble has not been touched. The presence of even a very small amount of mercury in solution will render the zinc fragile. The mercury is precipitated from solution on the zinc, with which it amalgamates, and causes its disintegration. As most of the old tailing available has resulted from the treatment of ores by amalgamation, they generally contain some floured mercury. On weathering, this finely divided mercury becomes mercuric oxide, which dissolves at once in cyanide solution. 'Short zinc' and poor precipitation often follow from the use of dilute solutions containing no or very little free alkali. In one case coming under my observation, cyanide treatment followed directly after stamp-milling and amalgamation. Milk of lime was continuously added to the stream of pulp after it left the plates, and the sand was caught in collecting vats. After draining, the sand was transferred to leaching vats, and a first solution run on. The sand contained some concentrate (sulphides) which oxidized readily, and it was noticed that the first solution drawn off was always acid, although there was a small excess of lime in the sand. The solutions which were drawn off subsequently were in good condition, and when mixed with the first solution, a bulky flocculent precipitate came down. This precipitate coated the zinc, and the precipitation of the gold was poor. By mixing the contents of the gold tank thoroughly and regulating the amount of free alkali in the solution, the precipitation became regular and satisfactory. In many cases it will pay to run the gold tanks intermittently, that is to say, to fill one gold tank with solution, and then turn the effluent from the leaching vat to another gold tank. The contents of the first gold tank should then be agitated and brought to a suitable condition for precipitation. In most cases, this will mean the addition of the proper amount of lime or caustic soda to give that degree of alkalinity to the solution which proves most favorable to precipitation. After allowing suspended matter to settle, or after filtering it off, precipitation of the gold and silver will take place under the most favorable conditions, and 'high' sump-solution need no longer be feared.

A very interesting article by A. J. Clark appeared recently in the *Journal* of the Chemical, Metallurgical and Mining Society of South Africa (Vol. 9, p. 222), in which a comparison of results and costs in precipitating by zinc shavings and zinc-dust is given. The results quoted by him show that the cost of zinc-dust precipitation is much less than precipitation by shavings. This paper is well worth the attention of the users of zinc shavings, and should cause them in

many cases to try to improve their practice. The proper equipment of the precipitation and clean-up departments in plants where zinc shavings are used has received too little attention, and in many cases only the most perfunctory care is taken of the precipitation, with the result that much zinc is wasted and the cleaning up of the boxes and melting of the bullion is unnecessarily laborious and costly.

BERTRAM HUNT.

San Francisco, May 11.

The Editor:

Sir—In your issue of April 3, F. L. Bosqui speaks of short zinc and brittle zinc as though the two were the same. There is an important distinction between the two, and the causes which give rise to their formation are quite different. Those who have had experience in the treatment of old pan amalgamation tailing are quite familiar with brittle zinc, and understand the important part it plays in the precipitation of gold from the solutions, particularly from those containing copper derived from the bluestone used in the old Washoe process. The brittleness is due entirely to the quicksilver which is recovered from the tailing and precipitated on the zinc. Within a few hours from the time the solution is turned into a freshly packed box, the shavings in the upper compartments turn white and become so brittle that a large mass can be compressed into a small compact ball. The precipitation of the quicksilver is so complete that in a 16-ft. box of nine compartments only the three upper ones will contain an appreciable amount of brittle zinc, the rest showing the brilliant hue of the copper which comes down after the quicksilver. When the zinc is thus coated with quicksilver the precipitation is complete. Boxes containing this kind of brittle zinc have to be looked after most carefully. My usual practice has been not to repack the compartments containing the brittle zinc until the zinc has practically disappeared. This point cannot always be determined by inspection, as the zinc often retains the outward shape and bulk of the original shavings.

There are probably other causes which give rise to brittle zinc, but I question their importance. Very often in cleaning up the boxes a certain amount of material of doubtful composition, having the outward form of shavings, will be found. This material is brittle and contains, among other things, certain zinc compounds formed by the replacement of a part of the original metal. This type of brittle zinc usually forms in badly packed boxes, where the circulation is poor and where the shavings have not been properly loosened previous to packing. I question whether this material can be properly classed as brittle zinc.

By 'short zinc' I mean that which is discovered in cleaning up the boxes and which ranges from a fraction up to 3 or 4 in. long. The objectionable feature about this is that it refuses to be made up into a fluffy mass like long zinc, and if replaced in the boxes in any considerable quantity it will retard the flow of the solution, and will perhaps cause the box to overflow. The material can be given an acid treatment, or may be roasted, but both of these are objection-

able. Short zinc of this character is wholly unlike brittle zinc, and refuses to break up or permit itself to be made into a compact mass by mere pressure. It is my opinion that short zinc is caused chiefly by the method employed in cutting the shavings. The greater portion of the zinc used is cut on lathes which do not produce shavings of uniform thickness. Furthermore, the lathes are so designed that in order to have a fair capacity they have to be run at such a speed that sufficient heat is generated to produce considerable oxidation. In designing a zinc-lathe, the problem is to transmit the power from the shaft on which the mandrel is mounted and around which the zinc is wound, to the screw driving the cutting tool. The mandrel revolves at somewhat more than 100 r.p.m., while the screw is driven at less than 1 r.p.m. The usual practice is to cut the speed down by a ratchet and pawl movement. This method is effective and cheap, but it has the disadvantage of imparting an intermittent movement to the screw, which in turn causes the cutting tool to advance by jerks, so that the shavings produced are not uniformly thick. Ordinary observation will fail to disclose any variation in the thickness, for the reason that the shavings are extremely thin, but a little consideration will show that the point which I bring out is correct. Another fault with most lathes is that the mandrel around which the zinc is wound has not a sufficiently great diameter, and the zinc has not the necessary time to cool before it again comes under the edge of the cutting tool. Of still greater importance is the matter of reducing the speed of the mandrel. Many manufacturers advise running their lathes at a speed of 120 r.p.m. or more. I do not know of a lathe made, with one exception, which should be run at a speed greater than 90 revolutions, while 80 would give better results. The exception which I have in mind is one which is run under ideal conditions, with special precautions to keep down the temperature of the zinc. The lathe cost something like \$2000, so it is not likely to come into general use.

Not long ago I ordered a considerable quantity of cut shavings from a manufacturer, and on receipt of it I found that the shipment was made up of two lots. One of these had been cut on the expensive lathe of which I have just made mention, and the other on a lathe having an intermittent feed. This gave an excellent opportunity to compare the two kinds of shaving, so I had the zinc-boxes packed so that if there were any difference it would be clearly shown. Each pair of boxes had exactly the same grade of solution and the same quantity. On cleaning up, the box containing the zinc cut on the expensive lathe gave about four pounds of short zinc, while the other yielded about forty-five. These results were in confirmation of a point which I had long maintained, namely, that the amount of 'shorts' produced depended upon the character of the shaving. It is a well established fact that where the shaving becomes heated during the process of cutting, so that a slight oxidation has taken place, the precipitation on those shavings will be imperfect, and I will add that an excessive amount of shorts will be produced in the boxes.

I believe that the points which I have dwelt upon have long been recognized by others, for a great many companies make use of precision machine-lathes for cutting zinc shaving. To cut them on these lathes it is only necessary to put a wooden drum on a shaft held in the chucks. The speed reduction on machine-lathes is obtained by gears and worms, which causes the cutting tool to advance at a constant speed, and this produces a shaving of uniform thickness. The high cost of lathes of this type makes it impracticable for small plants to install them, but it is advisable to do so where possible. All lathes employed for cutting shaving should be carefully looked after and frequently babbited to eliminate as far as possible all lost-motion. The slightest change from a perfect alignment will cause a serious variation in the thickness of the shaving cut by the machine.

The disposal of the 'shorts' after a clean-up is a serious matter. Acid refining is expensive and troublesome, and roasting is about as bad. The way I usually handle this material, if there be any considerable quantity, is to put it into a separate precipitating tank and run strong rich solution through it slowly until the zinc practically disappears. This method is employed in zinc-dust precipitation where rich solution is run through the presses previous to a clean-up. This is not applicable to zinc shaving in the regular boxes, for the reason that only 'shorts' would be left behind, as the long zinc would dissolve first.

Short zinc is not as active as a precipitating agent as long zinc, and by careless handling during the clean-up operations its precipitating coefficient can be made zero. When the zinc is removed from the boxes it should be kept wet with either water or solution until it is replaced, and then it should be immediately re-covered with solution. When exposed to the air a rapid oxidation takes place and the zinc becomes hot. After this takes place, precipitation is slow and indifferent.

R. STUART BROWNE.

San Francisco, May 12.

William Morris Stewart.

The Editor:

Sir—I was much pleased to read in the MINING AND SCIENTIFIC PRESS of May 1 your fine tribute to the life and character of that sterling pioneer, the late ex-Senator Stewart of Nevada. You are eminently correct in stating that, as the father of the American mining law, he was "responsible for a departure from the time-worn customs of tenure in real estate that was revolutionary in principle and practice," and you have done a service to the mining men of the West in calling attention to this fact. Whatever its defects as a piece of special legislation, he was always ready with cogent arguments in its defense during his lifetime, and in his death it is only just that he should receive credit for the vast results accomplished under its provisions. The younger generation of mining engineers and operators, who had not the privilege of experiencing the humming days between 1850 and 1880, when the West was being

settled, cannot be expected to understand easily the circumstances and conditions that inspired Stewart and those back of him in fighting for such an unheard-of notion as extra-lateral property rights, and many are found in these days to condemn it as one of the most unfortunate of theories. Those who are so disposed (and generally they are not miners) should make themselves more familiar with the history of that marvelous thirty years, which transformed a rugged, trackless, and semi-arid region, half as large as Europe, and infested with savages, into a self-sustaining empire, an empire through which it was impossible to push a railroad without encountering such a flood of business that rolling stock could not be supplied fast enough to handle it. For the benefit of these 'young-bloods' among us, may I be permitted to say a few words about the American Law, and what it did for the West?

A new land needs people first, and capital later. The whole landless world is hungry for it. Given the opportunity to acquire its possession (not its usage on rental, or royalty, or any other form of servitude), and the best and hardiest spirits from every point of the compass will rush in to grasp the right; for it is a human right. It was the American homestead law that peopled the western half of the Mississippi Valley, and it was the American mining law that peopled the region from the mountains to the Pacific. Agricultural land can be found with comparative ease. Just keep on moving, with eyes open, and in due time one surely comes to a verdure-clad patch with a flowing stream by the side, that will satisfy the hunger of the landless one. Mines, however, must be painfully searched for, and they exist generally in rather forbidding regions; but give the inducement, and the prospector will appear on the scene. He also, like the farmer, deserves possession as the reward of his labor, the right to own his 'find' to the centre of the earth, the opportunity to acquire absolute title to it as long as he pays his taxes like the rest of his fellow citizens, the right to sell it to whom he chooses, the right to deed it in perpetuity to his descendants. That was the status contemplated by the Stewart law. It was American in principle and it exhaled the doctrine of human rights in every one of its sections and lines. It brought into the West the finest bunch of humanity that ever was congregated in one place or region. It founded an industry that, though yet in its youth, is without its peer in scope, activity, and attainment in any part of the world, and it has resulted in the establishment of a group of sovereign States of unparalleled vigor and enormous wealth. The prospector was at the foundation of it all. He discovered and located practically every one of the hundreds of thousands of veins, lodes, ledges, and deposits that are now pouring out indestructible and unconsumable wealth at the rate of more than three hundred and fifty millions of dollars per annum.

Senator Stewart was the man who gave the prospector and the miner their chance. He should have a monument to his memory at every railroad gateway into the mountains, and they should be built by the miners and mining engineers and mining operators

of today, who are enjoying the fruits of his broad-minded and wholly American character.

THEO. F. VAN WAGENEN.

Zacatecas, Mexico, May. 9.

Unwatering an Old Mine.

The Editor:

Sir—Referring to 'Unwatering an Old Mine', in your issue of May 8, if 'Problem' has no more data than he has given, and electric power is available (costs of other power are not given), an electric hoist will be necessary in any event. Therefore, why worry about pumps? Re-timber the working shaft as you bale it out, and, as you get more accurate data on the water flow, and other conditions warrant, calculate your pump requirements when you know your needs; but, unless there is a 'bug' somewhere, a 200-gal. bucket would enable you to approximate the location of the permanent water-level and so calculate your needs. Baling is simple, cheaply installed, nearly fool-proof. Many a mine is spending money on pipe, pumps, pumpmen, mechanics, and excessive superintendence, where a discarded skip or bucket could be adapted at small expense.

Referring again to the problem, if the mine be assumed to be half stoped out for twice the length of the 740-ft. drift, from surface to the 1000-ft. level, and for a width of 10 ft., the old workings would contain about 7,400,000 cu. ft. If it took two years to fill them, it would mean, disregarding leakage throughout the country, an average flow of 50 gal. per minute. The foreman guessed the flow at 25 gal. per minute.

Baling will probably enable 'Problem' to learn enough of this 27-year-old *antiqua* to decide whether he is justified in buying an electric sinker station-pump or put in the old reliable Cornish rig, another nearly fool-proof machine.

W. H. STAVER.

Hemet, California, May 14.

Sixteen to One Mine.

The Editor:

Sir—You do an injustice, unintentionally of course, to 'Old Sierra', by locating the 16 to 1 mine in Nevada county, per editorial in your issue of yesterday, May 15. Please correct, so that Sierra county may have its proper credit for this bonanza.

DU RAY SMITH.

Oakland, California, May 16.

[By inadvertence we did credit the wrong county with the phenomenal mine which has been pouring wealth into the pockets of Mr. E. H. Wilson and his friends, and we hasten to make our apologies to Sierra county and its sturdy folk. We hope they may discover many more mines rich as the Sixteen to One. The fact is that the Sixteen to One is just across the line, so near to Nevada county that we do not need to recant our compliment. It lies within the Nevada county 'sphere of influence', and we believe as big mines may be awaiting the courageous hunter there today as rewarded the efforts of the pioneer prospectors.—EDITOR.]

TESTING DREDGEABLE GRAVELS.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM H. RADFORD.

I consider dredging the safest method of placer mining, when carried on intelligently. 'Carried on intelligently'. Let this phrase form the motif for my remarks. I will assume that capital is to be invested in the dredging business, and that a property is in view that is considered attractive. An engineer familiar with dredging should be engaged to report on this property, given a free hand, take his own crew in order to avoid any chance of salting, and have no restriction upon doing the work in his own way. He should first go over the property in order to size up the situation and determine as far as possible the nature of the auriferous deposit so as to lay out his plans for prospecting. Should he find the ground full of water, testing by means of drilling machines will be necessary, but if the ground be dry, or with a light flow of water on and near the bedrock, which can be controlled by a hand-pump or by an

Drill and Washing Apparatus.

ejector, the latter plan will be by far the more satisfactory. I will assume that the ground is found to be fairly dry in the upper part and wet in the lower, as frequently occurs, and that from the engineer's superficial examination he is led to conclude that the deposit is the bed of an old river or creek. Quartz mines known to have yielded good ore exist in the mountains at the head of the valley in question, or the country rock in the range above the property consists of schistose material with numerous thin quartz seams, and features which will lead our engineer to expect something of value in the alluvial ground in the valley below. Assuming that there are no side feeders in the form of tributary creeks that formerly flowed into the main channel, the best ground should be near the head of the property, and the first hole should be put down well to the side of the supposed position of the channel. I have generally used a No. 3 traction Keystone drill for drilling purposes. The outfit should embrace the following: the drill with plenty of 'spares' in the shape of extra shoes, extra couplings, a few extra lengths of casing, a couple of extra driving blocks, bolts, an extra driving cap, at least three drilling bits, extra sand-pump, valve, and leathers for the plunger. Also a 10-ft. sluice-box, 12 in. wide, inside measurement,

with sides 10 in. deep, having the bottom planed and the sides marked with saw-cuts every three inches for about four feet from the lower end of the box. These saw-cuts should extend to a height of 3 in. from the bottom, with every fourth one extending to a height of 6 in., to indicate the several foot-marks.

The sluice-box should be provided with cleats nailed to the sides at the extreme end, coming down to within an inch of the bottom, and a gate that fits loosely in the box and is held in place by the cleats.

Box Used for Cleaning
Carpet From Rocker.

The object in having the cleats come down to within an inch of the bottom is to allow of the box being quickly and thoroughly swept out after each pumping. A good light rocker should be provided, 5 ft. long, with 1/4-in. holes in the hopper, an apron, and a yard of brussels carpet on the bottom, held in place by three cleats, one at the head to prevent any of the sand getting under the carpet, and one at each side to hold down the edges. There is also needed a panning tub and pans, and a very fine sieve to be used for sifting out the particles of steel and iron that get chipped from the bit or casing. A hole should be dug below the discharge end of the rocker to act as a sump, so that when the pay-streak is being drilled, the tailing from it can be saved and returned to the rocker to be once more run through. As the pay-streak frequently contains a larger percentage of black sand, and occasionally coarse iron, there is a likelihood of some colors of gold being knocked off the carpet and going down into the tailing, hence the above precaution; though when I have had an experienced rocker-man I have seldom found that anything escaped the carpet.

Marked
Casing.

With the drill carefully lined up and accurately set over the first point to be tested, the engineer should have his drill-man mark off the shoe-section of the casing into one foot lengths, so that he can tell the depth reached by the bottom of the shoe after driving. The length of the first section should also be marked off on the drill-stem and on the sand-pump. After these operations have been performed, he is ready to start. A hole 18 to 20 in. deep is first dug with a shovel, and a pan of dirt for each one foot of depth of hole should be thrown into the sluice-box, in order to test the ground

not drilled through. The shoe-section of the casing is placed in the hole and is driven until it is firm, and until a depth of say two feet, as shown by the mark on the casing, is reached. The material in the casing is then measured by carefully lowering the sand-pump until the foot of the pump touches the solid material. Noting the distance in the pump-column above the top of the casing, this measurement is given to the engineer in charge, who enters it in his 'log'. The material in the pipe is pumped out and emptied into the sluice-box, care being taken to wash off the sand-pumps and foot-valve after each pumping. It is next moved down to the lower end of the sluice-box and measured by means of the before-mentioned marks. This gives the engineer a check on the measurements called out to him by the drill-man, and also shows the difference that sometimes exists between the measurement in the hole and the amount of solid material actually put into the box. When drilling in material containing clay, a slime will be produced, through which the sand-pump will settle, no matter how carefully it is let down into the hole, on account of which the measurement recorded in the log will be less than the measurement of the material discharged into the box. The amount in the box is what the engineer should record in his log. It is not often, however, that this varies materially from the amount given by the drill-man. The material in the slime-box is next washed forward into the hopper of the rocker, the box carefully washed and brushed out to get every color, and the dirt is then rocked. The apron, containing the bulk of the gold, is handed to the panner, who pans out the buckets while the carpet is being taken up and washed. To expeditiously clean the carpet thoroughly it is best to use a washer consisting of a short wooden trough with a roller set near the bottom. This trough is partly filled with water, and one end of the carpet, with the nap down, is placed under the roller and run up and down two or three times. This motion opens the seams in the carpet, liberating the black sand and gold contained in them, which fall to the bottom. The box is emptied into a pan and given to the panner, who adds its gold content to what he had obtained from the apron. The 'colors' from both washings are segregated and counted, and entered in the log. While all this is going on the drill-man has driven the casing down another foot, and if necessary has cut the material up with the drill so that it can be pumped out. This method is followed until bedrock is reached. Where the gravel is tight or is coarse in character, it is better to drill ahead of the casing before driving, for if this is not done the large rocks will be forced out of the way as the casing is driven down, and whatever gravel is under the rocks and in line of the casing will be pushed out of the way and lost to that particular 'drive'. To a drive of one foot the ground should be drilled ahead for about ten inches. In the log the following should be noted: the depth from which each pumping is taken; whether the ground has been drilled ahead or not, and if so, for what distance; the amount of the drive, usually one foot at a time when in gold-bearing gravel, or several feet when in

the top soil in loam, or in seams of clay; the amount of core obtained from each drive; the gold obtained, segregated into colors of various sizes; the character of the ground passed through, and the facility with which it is washed. When the hole is finished the total depth and amount of core obtained are taken and compared; if found to be alike, and if the different drivings and corresponding amounts of cores are similar, the hole is a normal one, and the value of the hole can be calculated in the usual way, namely, depth of hole in feet multiplied by 0.27 gives the theoretical cubic content in feet. Then the cubic content of the hole is to 27 as the value of the gold obtained is to the value per cubic yard. If, however, as is usually the case, the core is in excess of the theoretical cubic content of the hole, then such a proportion of the gold must be taken as the proportion existing between the ore obtained and the theoretical content. For instance, if 300 in. of hole is drilled, and 400 in. of core is extracted, and it is found from inspection of the log that the excess of core came from that part of the hole where the gold was being obtained, then $(\frac{300}{400} = 0.75)$ only 75% of the value of the gold obtained should be used in the calculation of the value of the hole as given above. If, however, the excess of ore occurs in the places where no gold was found, no attention need be paid to the excess, as the value of the hole will not be affected. All this should be readily deducible from inspection of the log-book. In this case that part of the hole from the surface to 4 ft. in depth, which gave only 4 specks, is ignored; also the part from 15 to 18 ft., which was sunk in bedrock and which yielded no gold. If this method be followed, and good judgment used by the engineer in deducing results from the facts given in the log, reliable values should be obtained which should afterward be closely verified in dredging. One of the dredging companies in Oroville found, in working a piece of ground which I had drilled, that the values obtained agreed almost exactly with their drilling results, and the logs were so correct that they were kept posted in the pilot house for the guidance of the winchmen. In Montana, the Conrey Placer Co. made some careful tests, whereby a difference of only 5% was found between the dredging results and the drilling values. It is a case of 'the man behind the gun', and I feel confident that when the method outlined above is followed, and sufficient holes are drilled, the final dredging results will be found to agree closely with the drilling values. After bedrock has been reached the casing must be pulled, in order to proceed to the next hole. A contrivance known as a 'monkey-pole' will aid materially in this operation, where the casing comes up with difficulty. It consists of a pole about 25 ft. long and 10 in. wide, flattened on one side. The butt end is beveled so as to allow it to fit under a block of wood that is attached to the casing by means of a stirrup just large enough to slip over the couplings, and which will jam and hold the casing when tilted by the pole. The pulling jars are attached to the drill-rope and lowered into the casing, the block is fastened to the casing and the sand-pump rope, detached from the sand-pump, is tied to the upper end

of the pole. The butt end of the pole is placed under the block, and a pillow-block, hollowed out to take the round side of the pole, is placed on the ground close up to the casing, to act as a fulcrum. The upper end is pulled until the pole forms an angle of about 20° with the ground. Two or three men walk up the pole and the pulling of the casing commences. The combined weight of the men at the end of the line, and the hammering of the pulling jars, soon starts the casing, which quickly comes up. As soon as the end of the pole touches the ground the men jump off, the pole is pulled up again, and the operation is repeated. Each time that the pole is raised the drillman knocks down the block attached to the casing and takes a new hold with the chain tongs, to prevent the block from slipping up on the casing. After a few feet of casing are pulled it will generally be found unnecessary to continue the use of the pulling-jars, and they can be dispensed with. The remainder of the casing is quickly pulled by means of the pole alone.

Hole No. 1 being finished, and a value of say only three cents per yard being found, indicates that the

Monkey-Pole Pulling Casing.

first hole is outside the dredgeable channel. A move toward the channel of 100 ft. should be made, and hole No. 2 put down. Here I assume a value of 20c. per yard is obtained. This shows that the channel has been reached. The drill should be moved back 50 ft. and hole No. 3 put down. At this point 6c. per yard is found, and assuming that the ground is fairly loose, this may be taken as the edge of the dredging area. The drill should then be moved 50 ft. ahead of No. 2, and hole No. 4 drilled, and holes every 50 ft. put down until the limit of 'pay' is reached on the other side of the channel. Should any very high-grade holes be drilled, extra holes are needed on either side, say 25 ft. away, to determine whether there is a local patch of high enrichment or whether there is a fair width of it. If it is found to be only a patch of high-grade ground, it is safer to eliminate the high value and to substitute the average of the holes on either side of it. When the first line of holes is finished, a second line can be started 500 to 1000 ft. farther up the channel, depending upon the length of the ground to be examined. The same method of procedure is then carried out. If, however, it is known that this part of the ground is not as wet as the lower part, it will be well to put down shafts instead of drill-

holes, and even if some water is found, an ejector run by steam from the boiler of the drill will be found a very efficient means of handling it. It takes up practically no room in the shaft. The shaft should be as small as possible, in order to save handling too much material, 2 ft. 3 in. by 4 ft. making a good size to work in, if the ground does not have to be timbered. It is convenient from the fact that every

Open-Link Dredge, Foot's Creek, Oregon.

three feet in depth gives one cubic yard of material. If the results of the holes in line No. 2 are somewhat better than those found in line No. 1, it is fair to assume that the channel is a normal one, and the third line can be started at the same distance above No. 2 that the latter is above No. 1. When sinking shafts, note should be made of the size of the largest rocks encountered, character of the bedrock and gravel; also the presence or absence of any beds of clay or cement-gravel. After the ground has been prospected the engineer should plot all the holes on a map, showing the boundaries of the property, and with the data in hand determine the number of cubic

El Oro No. 1, Close-Connected Dredge.

yards of material to be dredged that will yield a profit. Assuming that he has found that throughout the property the gravel is generally loose in character, free from large boulders, and that there are no beds of clay, then a dredge with $7\frac{1}{2}$ or 8 cu. ft. buckets could be decided upon. Such a dredge will have a safe capacity in the above described ground of 100,000 cu. yd. per month, and a working cost, under normal conditions, of about 4c. per cu. yd. The engi-

neer can now determine quite closely the life of the property and, knowing the price to be paid for the ground, and the cost of the dredge, he can intelligently advise his principal whether he should undertake the venture or not. He can state what profit may be expected, and what amount should be set aside annually to finally reimburse original capital. Costs of 3.5 to 2.15c. per cubic yard may be obtained with varying sizes of buckets. When the gravel is mixed to some extent with clay, it is tough, but when the boulders are not large, the dredge with close-connected buckets, shaking screens, and single sluices works well, and when using a 5 cu. ft. bucket it will work at a cost per yard varying from 5.5 to 9c., depending on the toughness of the ground. When beds of clay interfere with a free-working gravel, and the boulders are not large, the close-connected bucket dredge, with buckets as free from interior projections as possible, will do the best work, and will show a cost with 5-ft. buckets of about 6c. per yard. In the latter ground the gold-saving appliances should be so arranged that when the clay is being dug it should be passed off the boat through a different set of sluices from those over which the gravel is passed. Clay, when it is plastic and rolls up into balls, will rob the riffles of gold with which it comes in contact. By adoption of the above suggestion this loss will be avoided, without interfering with the working of the dredge. The change from one set of sluices to the other is regulated by the winch-man without closing down the boat. Where the gravel contains many boulders of large size the bucket-and-link (open-connected) style of boat will give the best results, as very large boulders can be taken up in the bucket-line, as is done at Ruby, Montana. Here the last boat, No. 3, having 12½ cu. ft. buckets, and digging about 100,000 cu. yd. per month, is showing a working cost of 8c. per yard. From experience in Montana, Colorado, and California, it may be said that dredging can be carried on throughout the year in any part of the United States. In the cold climates in winter there is required the addition of steam-heating apparatus on the boat; housing in of the exposed parts of the stacker and bucket line, with flooding of the ground to be dredged. In analyzing the cost-sheets of several dredging companies I find the item of repairs very prominent; in fact, it is almost the largest item; and it occurs to me that if more attention were given to loosening up the light ground, which is the main cause of the breaks and the severe strains on the boat, a material reduction in repair costs and in the total cost per yard could be effected, partly because of the increased digging capacity. Where the ground ahead of the dredge is drilled, as is often done to serve as a guide to the dredge master, a very slight additional expense for blasting these holes would bring about the desired result; and even where the ground is not prospected ahead this method could be advantageously applied. Dredging, owing to the closeness with which a properly built boat will save the values (85 to 90%), is the best form of placer mining, and capital, guided by an engineer familiar with the work, can be assured of successful results.

THERMIT WELDING.

Written for the MINING AND SCIENTIFIC PRESS
By DOUGLAS WATERMAN.

The Goldschmidt thermit welding process has been in use for a number of years. While serving a great variety of purposes, its chief employment has been in the welding of rails for electric traction lines, and in repairing broken locomotive frames.

A new use has been found for thermit welding in connection with dredge mining in California. The Boston machine shop at Oroville has lately undertaken the repair of cracked and broken bucket-bottoms, gear-wheels, and other heavy castings which had been thrown on the scrap-pile. It was here that my attention was first drawn to the process. The welding has proved remarkably successful. Cracked bottoms repaired by this process have served in the bucket-line more than 90 days, and so far have shown no sign of weakness. The cost of repairing a bucket-bottom did not exceed \$15. The scrapping of such a casting would have entailed a loss of \$80. Those accustomed to operating in remote countries where transportation is difficult or impossible for several months in the year, will appreciate the value of a process that affords means for repairing vital parts of machinery in a day's time. It is no exaggeration to say that in many cases thermit would be worth its weight in gold.

Thermit is a mechanical mixture of aluminum and an oxide of another metal, iron being the one that is of commercial value at present. Experiments are being conducted with copper, in the hope of reducing the temperature sufficiently to avoid volatilization of the metal. That has been the difficulty in the way of thermit-copper welding.

It is possible by the admixture of suitable quantities of other metals to the thermit, to produce the best quality of the steels of those metals, such as nickel, manganese, and chrome steel. Preparations for making the various steels are obtainable. The chemical reactions are simple. The aluminum combines with the oxygen in the metallic oxide, forming a slag, and iron is set free. The heat of the reaction reaches a temperature of 5400° F., which is 2000° above the melting point of steel. It is this surplus heat that does the welding. The slag which results from the combination of the aluminum and oxygen is corundum, Al_2O_3 , plus some aluminum silicate. It is equivalent to one-half, by weight, of the original thermit. Thermit itself is not combustible and may be handled with perfect safety. Once, however, that chemical action is started, the reaction progresses with great rapidity, from 20 to 30 seconds only being required for complete separation of the iron from the slag. Chemical action is started through the agency of an ignition powder. Unlike the thermit, the ignition powder is highly combustible. It is well to mention here that the tin box containing the powder should be kept covered, to protect it from the danger of flying sparks.

The apparatus required for making the weld is a gasoline torch connected to an air-receiver, and a thermit crucible. The crucible is funnel-shaped, and of a size suited to the quantity of metal required. It

is made of sheet-iron and is lined with a preparation of 'magnesia-tar'. This material greatly resembles, both in appearance and in its action under heat, the asphaltum used on city streets. A magnesia rim is inserted in the small end of the crucible, an inner mold of cast-iron placed in position, and the space of $\frac{3}{4}$ to $1\frac{1}{2}$ in. between is tamped with the material, which has been previously heated in an open pan. The crucible is then dried in an oven. The shell is made thickest at the bottom, where the greatest

Filling the Mold; 30 Seconds After Lighting.

action is produced. In preparing for the weld a 'thimble' of magnesia is placed in the bottom of the crucible, the $\frac{1}{2}$ -in. hole serving as a channel through which the thermit steel is poured. A tapping-pin is suspended inside the 'thimble'; on this are placed asbestos washers, a metal disk, and a quantity of refractory sand; the crucible is then filled with the required amount of thermit. In repairing cracked or broken shafts, connecting rods, and other heavy square or round parts of machinery, it is usual to leave a collar of thermit steel, an inch or more in thickness around the weld. The number of cubic inches of metal that will be required to form the collar as well as to fill the fracture are calculated. This number multiplied by the factor 0.28 gives the weight of the steel. For small castings it is customary to use twice this weight of thermit. For large castings, where the cost of the thermit is considerable, $1\frac{1}{2}$ times the weight of the steel may be taken, and the difference compensated by the addition of soft steel punchings. Any material added to the thermit should be thoroughly mixed with it, so as to produce a uniform steel. The broken parts should be carefully prepared to receive the thermit steel by thoroughly cleansing them of grease and oxide.

There are two methods of forming the mold. In the first, wax is used to fill the crack and to build up in the form of the collar. 'Green' or molders' sand is mixed as for iron founding, except that the sand which is to come in contact with the molten metal should have a larger proportion of fire-clay. The addition of powdered graphite is beneficial. A wooden box is built around the casting, and the sand is carefully tamped in place. A pouring-hole and a 'riser' are left on top, and at the bottom is a hole through which the wax can drain when melted. The success of the weld depends upon heating the casting sufficiently to prevent sudden chilling of the molten metal. To secure the necessary heat, compressed air must be used in connection with the gasoline torch.

With the ordinary gasoline torch under pressure alone, insufficient oxygen is supplied to the flame—when directed through the narrow channels in the mold. Compressed air is so extensively used in mining that this method can usually be employed. If, however, compressed air is not available, the second method must be employed. In this a pattern is made and the sand is molded as in foundry practice. The casting is heated to as high a temperature as possible, by the direct application of the gasoline flame. The final preparations must be completed before the casting cools. When the mold is in place, and the crucible suspended over the pouring-hole, a match is applied to the small quantity of ignition-powder placed on top of the thermit. A metal cover is quickly placed on the crucible, and in less than 30 seconds the contents become a seething mass of molten metal. The plug in the bottom of the crucible is driven inward by a sharp blow, and the liquid metal flows into the pouring-hole, filling the mold. An emery-wheel, connected to a motor by means of a flexible shaft, is sometimes employed to finish the casting when cool.

Many examples can be cited to illustrate the adaptability of thermit-welding, and the excellent service that the process has given under severe conditions. A striking instance of its value was in the repair of a brace supporting the outer bearing of the propeller-shaft of one of the North German Lloyd twin-

Bucket Bottom Repaired by Thermit. Thermit Steel Indicated by Arrows.

screw steamers. This was welded by means of thermit five years ago, and is still in service. Locomotive frames are constantly being welded by this process, the operation occupying but two days, while at least that number of weeks would be required to repair the frame in the usual way.

The total cost of the buildings erected in the principal cities of the United States in 1908 was \$546,467,390, according to Jefferson Middleton, of the United States Geological Survey. New York ranked first, the cost of its buildings exceeding those of its closest competitor, Chicago, by \$50,584,582, or more than 75%. If the cost of operations in Brooklyn, the third city in rank, is added to that for New York, the total will be \$163,684,622, or 30% of the cost of the building operations in 49 cities. San Francisco is fourth in rank, Philadelphia is fifth, and St. Louis is sixth. Seventh in rank is Seattle, which spent more for buildings in 1908 than Pittsburg, which was eighth, or Boston, which was ninth.

HIGH EXPLOSIVES AND SAFETY-FUSE.

By EDGAR TAYLOR.

*Progress has been continuous and rapid in the breaking of ground, the greatest advance being the substitution of high explosives for the now almost obsolete gunpowder in blasting. In fact, it would not be too much to say that the invention of high explosives and safety-fuse mark the two most forward steps in the mining history of the last century, and to these, more than to any other cause, is to be attributed the rapid speed of development possible today.

High explosives, in contradistinction to black powder and the like, have been defined as explosives which require initial detonation, that is, the use of a detonator. It was Alfred Nobel who, prior to his invention of dynamite, conceived the idea of this initial detonation, which he first applied to nitroglycerine as early as 1864. Dynamite, which was invented in 1867, was the first high explosive used, and remained practically the only explosive of its kind until Nobel, in 1875, invented blasting gelatine. The figures given in a paper read by the inventor before the Society of Arts in May 1875 show the quantities used in the first years of the introduction of dynamite to have increased from 11 tons in 1867 to over 3000 tons in 1874. With the introduction of blasting gelatine in 1875, and the modifications known as gelatine dynamite and gelignite, the use of nitroglycerine explosives became more and more general whenever hard rock had to be dealt with.

In 1864, explosives of the 'Sprengel' type, the first representative of which was a nitrate of ammonia compound known as the 'Favier' explosive, termed in this country (England) 'Miners' Safety Explosive', were introduced, and in course of time these nitrate of ammonia explosives, of which numerous modifications were devised, have become the leading explosives in coal-getting, because of their relative safety in the presence of fire-damp. Several nitroglycerine explosives, such as carbonite and saxonite, in which the temperature of the flame is reduced either by an excess of carbonaceous substance or by the addition of salts, such as oxalate of ammonia, sulphate of magnesia, alum, etc., have likewise been added to the list of so-called safety-explosives.

The displacement of black powder and other similar mechanical mixtures, by high explosives, was concurrent with the recognition of the relative cost of the explosive, plus detonator and fuse, as compared with the cost of the bore-hole: the harder a rock the higher is the cost of the bore-hole and the more desirable it is to blast with high explosives of high density, thus obtaining the greatest amount of breakage with the least relative cost. Thus nitroglycerine explosives held their own and increased their field, while nitrate of ammonia explosives and those which, like them, are of lower density, were confined to coal getting and workings in soft rock and stone where the bore-hole was not costly. The relative densities are roughly 1.6 for nitroglycerine

explosives and 1.1 for nitrate of ammonia and chlorate mixtures, the density of tonite, which is a gun-cotton-nitrate of barium mixture, being about 1.2. It is self-evident that, the advantage of density being recognized, black powder was bound to be replaced by high explosives wherever the bore-hole was difficult to make.

The introduction and gradual development of rock-drilling machines still further accentuated the necessity of using explosives of high density and considerable strength, as it became possible to make the holes deeper and relatively less in number. Thus, for instance, mining on the Rand is almost exclusively done with blasting gelatine, which is the strongest explosive known, while in quarrying less powerful explosives are needed. The evolution in the use of high explosives is therefore essentially an economic question; although on the other hand it is of importance to remember that certain classes of rock can only be dealt with by means of high explosives, the selection of the right explosive for the particular work being therefore of considerable moment; and the relative cost of boring has always to be borne in mind.

Previous to the invention of safety-fuse the devices for conveying fire to the gunpowder charge were of the most crude and primitive description. Sometimes a small trail of fine gunpowder paper; sometimes quills plucked from geese, filled with fine grain powder, and lengthened where needful by the insertion of one quill into another; while, oftener still, rushes were used, the rush having been first split, the pith scooped out, its place filled with powder, and the two halves bound together again with fine string. The frequent accidents resulting from the use of explosives in tin and copper mining, chiefly owing to the uncertain duration of the time between the lighting of the rush or quill and the exploding of the charge, led Wm. Bickford, of Tuckermill, in or about 1830, to turn his thoughts toward the invention of some method whereby blasting operations could be conducted with the minimum of risk to the miner. His motives were purely philanthropic; it remained for his successors to turn his invention into an extensive and legitimate commercial enterprise. In 1831, Mr. Bickford took out his first patent for 'miners safety-fuse'. His object was to provide a protected core of powder, thin and continuous, along which the fire might travel slowly at a uniform and determinate rate of speed. This result he obtained by causing a number of jute threads, passed through an orifice and stretched by means of a weight attached to their extremities, to rotate slowly, while, at the same time, a small current of fine powder fell into the tube thus formed, and was retained as a slender core. This fuse was further protected by a covering of strong twine wound thereon at nearly right angles to the former twist by an operation called 'countering'. It was then immersed in a bath of heated varnish, and a coat of whiting applied to prevent it sticking together when coiled. Subsequently it was found, for use in damp and wet places, to require an additional coat of tape, applied spirally and insulated in an extra varnish, while the exigencies of shaft-sinking

*Abstract from Presidential Address before the 18th Annual Meeting of the Institution of Mining and Metallurgy.

and other rough and wet conditions, soon suggested the addition of another coating of tape and varnish, resulting in the well known double-tape fuse. It was still in the eighteen-thirties that George Smith brought the Bickford fuse under the notice of the War Office and Royal Engineer authorities, and soon after its first adoption by the Government the advantages of the safety-fuses were also brought before a committee of the House of Commons, this being one of the earlier of the long series of examinations as to means for minimizing the danger in mines. A critical period in the history of the safety-fuse was reached when the invention of higher explosives led to the adoption of the capsule of fulminate, now termed the detonator, as a universal intermediary between the fuse and the charge. Such difficulties as were found to exist, however, were soon overcome.

METHOD OF PLOTTING MINE-ASSAYS.

Written for the MINING AND SCIENTIFIC PRESS
By EDWARD H. NUTTER.

The following method of graphically plotting mine-assays was devised for use at the Liberty Bell mine. It was designed with a view to correlating assays and indicating the trend of ore-shoots, so that intelligent exploration could be easily planned for unopened blocks of ground, on the basis of values found in adjoining drifts, stopes, and raises. It is required of samplers at the Liberty Bell that all of their descriptions give the co-ordinates of the points at which the samples were taken; and it is an easy matter, therefore, to plot the assays afterward. Complete descriptions are entered as well in a card-file. The vein is sampled at regular intervals as work

Method of Plotting Mine Assays.

with the result that safety-fuse is now uniformly employed with the higher explosives as it had formerly been with gunpowder.

The Cruikshank gold-quartz mine in Monterey county, California, is credited with having produced \$25,000 in gold, and much specimen quartz was also afforded by this mine. A Huntington mill was installed in 1887, and ran for about six months. This mine, also called the Last Chance, is in the Los Burros mining district, about 20 miles southwest of Jolon. Considerable placer gold has been taken out of the region about Jolon from gravels along the Nacimiento river and elsewhere. From the La Panza district, in San Luis Obispo county, considerable placer gold has been extracted. No gold quartz mine ever yet paid in the California coast ranges, but recent discoveries have been reported from San Carpajaro, in San Luis Obispo county. The ore is claimed to be rich. The Last Chance, or Cruikshank, cost the owners \$70,000, and came into possession of the Bank of California for a debt.

Seigniorage, or profit on coinage of silver by the Government, in 1907, the last year reported, was \$9,095,044. In the last 10 years the Government revenue from this source has amounted to \$75,684,972.

advances, and the plotted values of these samples give a bird's eye view of their distribution in the worked portions of the vein. In the original map, different ratios of gold and silver in the assays are shown by different colors of the symbols. Thus: If gold gives over two-thirds of the value to an assay, the symbol is red; between two-thirds and one-third, blue; and less than one-third, black. The figure shows the plotted assays of a small abandoned stope in the western end of the mine. The symbols were chosen so that a sharp differentiation between mill-rock and waste could be made at once by inspection.

Radio-activity of the rock passed through by the Simplon tunnel was made by Mr. Gallo, employing the Curie instrument, modified by Debiérne, for measurements. Calcareous gypsum rocks and those comprised in the calcareous schists he found to be perfectly inactive, or very feeble in radio-activity. Orthogneiss, on the contrary, is perceptibly radio-active. The maximum dispersion was 43.2 volt-hours. Radio-activity was noted generally in rocks containing minerals like titanite, zirconium, etc. These measurements agree with those made by Borne in water from the Simplon tunnel, who found that the springs richest in emanations flow from gneiss and granites. Rendiconti della Societa di Roma.

months use, but may break again at the same point. Fig. 2 shows a spud which would have fulfilled its purpose except for an error in the drafting room. The rabbets in the cast-steel shoe were intended to permit the insertion of the shoe in the beam without interfering with the two main inside web plates. These rabbets were cast at right angles to their proper direction and consequently it was necessary to cut off the inside plates above the shoe, thereby making the spud only approximately half as strong at this point, where the spud actually broke.

This occurred after four years use. By this time most of the hard deep gravel had been dredged, and the spud was repaired in a manner that left it with the same strength that it originally had. This was accomplished by simply cutting off the main beam entirely on the lower end up to the break, a distance of approximately 5½ ft. The original outside plates were taken off so access could be had to the inside plates, shown in section XY, Fig. 3. These were then cut off so as not to interfere with the steel shoe which was then inserted and riveted as before. Care-

Fig. 3.

less riveting, in the case of even properly designed spuds, often leads to trouble. The web plates soon show signs of weakening when a rivet starts, and this is a danger to which the constant jarring exposes them.

In very deep ground, torsional strains caused by the swinging of the dredge on the spud are taken care of by cross-bracing. In such ground breakage occurs some distance above the point where the spud is of uniform strength. Construction has been made heavier and heavier with the increased capacity of dredges as the result of experience, which is the only reliable guide. Now among those who know, little doubt is felt regarding spuds recently designed and installed.

The ganister quarried in Blair county, Pennsylvania, is used for making refractory brick for furnace linings. It occurs as a bed or beds in the formation known by geologists as the 'White Medina' sandstone, which forms the crests of Tussey, Lock, Loop, Dunning, and other mountains. Practically all used at present is obtained from boulders that mantle the mountain sides, having rolled down from the higher ridges. The supply available in this way is very great—luckily so, as the natural rock is difficult and costly to quarry. The qualities of ganister that make it suitable for refractory brick are disputed, but seem to depend chiefly on its greater strength.

SILVER ISLET VEIN.

Silver Islet, according to Walter McDermott, is a small island, a mile and three-quarters from land, in Lake Superior. It is a portion of a long diorite dike cropping at intervals and making islands, and the famous silver vein showed clearly under water to the northwest. Coffor-dams were sunk and the whole island was built up, and the workings were ultimately carried to a depth of 1200 ft. below water. The vein itself had two branches. The dike was faulted, and there was a branch vein, an east vein, and another vein branching to the west. At various points, to a depth of 360 ft., plumbago occurred freely through the diorite, and in the neighborhood of the plumbago the silver always occurred. Roughly, the plumbago impregnation was a pear-shaped mass, generally surrounding or near the junction of the two veins. On the various levels, down to 360 ft., the occurrence of silver was plentiful, and the production in a comparatively short length of the levels was about two and a half million dollars. The occurrences of silver

were chiefly in the upper part. At 360 ft. the plumbago ceased, and the silver also practically ceased. Afterward an inclined shaft in the body of the dike was sunk to a depth from the surface of about 1200 ft. Diamond-drill holes were run in various directions, but no silver worth mentioning was found below 360 ft. where the big mass of plumbago occurred. Furthermore, it was found that the silver tended to occur where a change of rock existed. At the various points where there was a change from slate to diorite the silver nearly always occurred in valuable quantities. Going out into the slate on either side no silver of any consequence was

found. The country rocks were the pre-Cambrian above the Huronian series. At about 360 ft. gas was found in the cavities in the rock, and on several occasions one or two men were burned. From one drill-hole the issuing gas burned for a length of about 150 ft. along the back of the level when first tapped. The men crawled in and plugged it, and even then it burned for a number of weeks, until the pressure was exhausted. The production of that gas and the existence of the graphite, and the co-existence of the silver with the graphite in the country rock were most striking facts. The whole history of the work at the mine showed that they had an evident connection with each other—the diorite rock, the impregnation of plumbago, the neighborhood of the branch veins—as that was the only region in which any payable ore was found. In connection with the recent discoveries of native silver at Cobalt, it was interesting to note that at the Silver Islet also nickel and cobalt and arsenic in various proportions existed with the native silver and the sulphide of silver, and with a certain amount of base minerals, zinc-blende, and galena.

It was only in the neighborhood of the plumbago that the silver seemed to enter into either the zinc-blende or the galena, perhaps merely as finely divided native silver.—(Institution of Mining and Metallurgy.)

METHODS OF COPPER MINING.

By H. LIPSON HANCOCK.

*In any attempt to compare the practice of various places, particularly in regard to costs of mining operations, due allowance must be made for differing local conditions. In the Western States of America and in the Spanish mines, there are immense mineral deposits which enable work to be conducted on a scale impracticable elsewhere. In America wages are high, in Spain they are low, consequently in the former mechanical devices are installed wherever practicable, while in Spain not even stone-breakers are used—hand labor being cheaper. Some mines possess natural advantages not found elsewhere. Open-cut methods may be possible, or the ore may be suited to direct smelting, thus saving the preliminary costs and losses of mechanical concentration; or, as at Rio Tinto, it may be amenable to treatment by a very cheap wet process. Cheap supplies of fuel and mining timber, as well as proximity to the seaboard, are obvious advantages as affecting costs of production.

The magnitude of operations has generally a very important bearing on costs. Where circumstances justify a heavy capital outlay on machinery, labor costs will obviously be lower than where no such expenditure is justified. In smelting operations, some transport appliances which work well and afford considerable economy on a large scale would be ineffective with a smaller output, where in many cases it would be best to make intermediate products and allow them to cool, notwithstanding the expense incurred in breaking, handling, and re-melting. General charges are often the same in amount, notwithstanding the amount of work done, and thus impose a heavier burden on small than on large tonnages. Other things being equal, an increase of output tends to decrease the cost per ton treated, especially in the smelting. While it may be interesting to compare the costs of various operations at mines and smelting works, no results of value can be reached without careful consideration of all the surrounding circumstances. Judged by the only equitable standard (the nearness to the best possible results), there may be cases where the lowest cost is least creditable to those concerned. If the advantageous conditions which are often to be found in connection with mining and smelting elsewhere existed in Australia, no doubt their methods in a number of instances could be adopted by us to good purpose. In making comparisons, however, our own special circumstances have to be borne in mind.

In the Wallaroo mines the rock is heavy and treacherous. Any relaxation of precaution and the adoption of more wholesale methods of breaking would involve the greatest risk of disaster, somewhat analogous to what has twice happened recently in Eastern Australia. I observed abroad no methods of working which, in my opinion, could be substituted to advantage at Wallaroo mines. Our present method by 'stye' and filling, which has been developed as the result of our experience, is as far as I

have been able to learn, the most effective for these conditions. The only other methods available for stoping the ground, apparently, would involve more cost, and at the same time afford less security to the men.

In underground haulage, if the rock were more stable and the lodes wider, the introduction of electrical or some other mechanical system of traction might deserve consideration, but under present circumstances hand tramming is the only plan adapted to the case. The arrangements for transferring material from one bin to a lower one in the shafts, so that quantities can be hauled from any one station, is as good as can be seen elsewhere. At no mine did I find a more economical system, or one that was less liable to cause hindrance. On the contrary, some of the important mines visited might with considerable advantage adopt our methods. Without our system of bin-winzes we could not handle our material in the quantities or at the cost that we do. Our cost of mining and hauling per ton of crude ore may therefore be regarded as quite satisfactory under the circumstances. Many mines are able to do this work at a much lower cost, but this is due to certain natural advantages which we are not fortunate enough to possess.

I did not see in my travels any plant so economical for copper-ore sorting as that at Wallaroo mines, nor did I meet anywhere results equal to our own, from concentrating machinery on which so little capital outlay had been incurred. I found no appliance capable of treating the quantities and working at so low a cost as our jigging machinery, and the alternative of a multiplicity of machines, each of small capacity, with complicated classifying arrangements, involves much greater primary cost, more wear and tear, and larger consumption of power. Our other concentrating machinery as a whole compares favorably. Re-crushing is always somewhat costly, whether done by ball mills, Huntingdon, Griffin, tube mills, rolls, or grinding pans. Ball mills produce less slime than do some of the other machines, which, for our work, is a great advantage. The larger or more modern plants in America are laid out in sections, each one a complete concentrating mill in itself. This arrangement serves a very useful purpose, as one or two divisions can always be kept in reserve, so that when a breakdown occurs, or machines require overhauling, the reserve section can immediately be put into commission, and repairs effected economically and without interruption to the work. While this provision would be very useful in our own works, it would involve considerably more capital expenditure, which we have always endeavored to avoid. Possibly it may be practicable at some future time to secure most of the benefit by duplicating certain parts of the plant. The percentage extraction of the copper at Wallaroo mines must be considered exceedingly satisfactory. A close watch is kept on the work done by systematic and careful sampling, and this is checked in such a way as to ensure reasonable accuracy. At Moonta mines the recovery by concentration is not so good as at Wallaroo mines, but taking into account the extraction by means of the cementa-

*Abstracted from the Australian Mining Standard.

tion process, our treatment as a whole gives a very high recovery.

The many important alterations in methods, appliances, and traffic arrangements carried out at the smelting works during the last year or two, are giving satisfaction, and the work at the sintering pots and blast-furnaces compares favorably with other places. The cost of charging the latter could be reduced by suitable bin arrangements, and larger furnaces could be utilized in the copper refining department, but the advantages are not sufficient to justify the outlay at present. In certain other departments minor improvements are being effectually made. The very important question of bessemerizing, which has long been under consideration, was the subject of very careful investigation, and there seems little doubt that it would result in considerable economy. Although the cost of electrolytic refining has been considerably reduced in recent years, it is still hoped to effect a further material reduction. The smallness of the quantities available for treatment, however, completely prevents suitable comparison with results achieved in the large American works.

In conclusion I may repeat that our heaviest costs are in the actual mining operations, and owing to the conditions under which the work has to be carried on, there is little prospect of effecting any material reduction. The recovery of metal contents in the dressing operations may be regarded as satisfactory, and the additional extraction at Moonta by cementation, although spread over a long period, forms an excellent extension of our treatment. At the smelting works the improvements introduced are giving satisfaction, and the opportunity for further material economy chiefly lies in the direction of bessemerizing. Apart from the last, our methods and appliances compare favorably with what are to be found elsewhere, making proper allowance for local conditions.

Fixation of Atmospheric Nitrogen. -F. Beck has invented an industrial process to extract nitrogen from the atmosphere. He has adopted a magnesium-tin alloy, which fixes nitrogen easily, and he recovers the substances employed. To prepare the magnesium-tin alloy, magnesium oxide is dissolved in melted carnallite, this solution being utilized as an electrolyte; the anode is carbon, and the cathode molten tin. Magnesium is formed at the cathode, which is dissolved in the tin gradually as it forms. When electrolysis is complete, nitrogen is bubbled through the molten mass, to which it is conveyed by an iron pipe coated with fire-clay. The magnesium melted in the tin is transformed into magnesium nitride, and the tin not attacked is recovered. The nitride is then treated with steam to produce ammonia and magnesium oxide. The latter may be again dissolved in the carnallite and, consequently, be utilized indefinitely.—*Métaux et Alliages.*

In the operation of the factories of the United States at the time of the last census there was required about 11,300,000 hp., of which, roughly, 77% was steam, 15 water-power, and less than 2% gas-power.

STEAM SHOVEL IN THE AMUR REGION.

*Recently M. G. Titoff, a mine owner of eastern Siberia, gave an interesting account of the installation on his property last season of a large endless-chain or bucket steam-shovel. This steam-shovel, which is to all intents and purposes a 'dry land' dredge, except that its buckets move in the opposite direction, was built at the Putiloff works in St. Petersburg and transported by rail to Sryetensk, over 5000 miles; thence by water, on barges, 400 miles to Jalindá, on the Amur; and thence hauled by horses 80 miles to the mines, on the river Urkan, a tributary of the Zea. The transportation charges were \$12,500, and the steam-shovel, with two locomotives, 65 cars, a mile and a quarter of track, cost \$57,500.

The chief difficulty to contend with was frozen ground. The spring was unusually late, and the steam-shovel was unable on this account to begin running at full capacity until June 23, although it started the middle of May. It ran night and day from June 23 to October 7, and handled a little over 175,000 cu. yd. It actually ran 231 eight-hour shifts,

Siberian Steam Shovel.

and averaged 762¼ cu. yd. per shift. The total product was \$60,000. The pay-streak ran 42c. per yard, and the cost of working, exclusive of interest charges, was 12½c., as against 29c. by hand-labor.

The estimates for the first season called for the handling of 200,000 cu. yd., running 60c. per yard. The lower tenor is accounted for by the fact that out of 4 ft. 8 in. of overburden only 1 ft. 9 in. was stripped, and the remaining material was taken out with the pay-streak.

Because of the frozen ground, Mr. Titoff conducts his operations along a trench 700 yards in length. On the sloping face of this cut the ground will thaw from 5 to 7 in. per day, and as the steam-shovel takes two days to work its way the length of the trench, this gives time for fresh ground to be thawed 10 to 14 in. between rounds. It is necessary to strip the overburden a year in advance, and this work is well done by the same steam-shovel. It handled soft bed-rock and gravel, even when considerably cemented, but found some difficulty with boulders weighing 100 to 200 lb. Altogether the machine seems to have been excellently built, and although the first season's run does not show much profit, it was creditable, considering the natural difficulties to be overcome, and a fine showing ought to be made this summer.

*Abstract from Gold and Platinum

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING PARTNERSHIP.

Several persons living at Walla Walla, Washington, made a trip to Crook county, Oregon, for the purpose of exploration, and especially for the discovery of a certain ledge of rock from which one of their number on a prior expedition had taken a piece of quartz afterward found to contain a large quantity of gold. They made a discovery of a quartz ledge which was thought to be the same ledge from which the piece of quartz was formerly taken, and several claims were located by the individuals for the benefit of all. After performing a little development work all returned to Walla Walla. Later in the year all of the members of the association except two made a second expedition, and when within a few miles of their former location one of them was given a piece of red colored quartz by a resident, who told him where it was found; other discoveries were made in the vicinity of the prior locations and some development work was done, and within a few weeks all returned home. Assays were made subsequently, and the red colored rock given to one of the parties by the resident showed gold in excess of \$100 per ton. No articles of partnership were ever signed, and no specific terms definitely agreed upon. Afterward three of the original explorers, together with two strangers, organized a third expedition and went to the place where the red quartz had been found, but were unsuccessful in locating what they thought to be the identical lead. They did, however, locate a claim at this place, calling it the Silver King, and at the same time they located other claims upon the same ledge and in the immediate vicinity. The Silver King mine was found to contain valuable ore, and a corporation was formed which took over all the claims located by these particular parties. Some time thereafter the other members of the second expedition who were present at the time, one of whom had received the piece of red quartz rock, claimed an interest in the Silver King mine and in all the property of the corporation, on the ground that the former incident led to the discovery of the Silver King mine, and consequently to the property of the corporation. In an action by such remaining parties to establish their interest in the corporate property the Court held that the information obtained at the time of receiving the red quartz from the resident was not a discovery, and that it was not known at the time that the rock possessed any value, and that whatever the original understanding or agreement may have been, it could not include discoveries subsequently made by any one of the members of the association, or by any different combination of some of such members. The original partnership agreement was limited to the two expeditions originally made, and when these expeditions were at an end, the right of all the members to share in the new discoveries of any member thereof, or of any new aggregation of part of its membership with others, was also at an end. The piece of red quartz, being 'float', did not indicate the position of the ledge whence it came. It showed that a ledge probably existed in that vicinity, but there was no discovery of a ledge, and all the members were in possession of the knowledge of the finding of the piece of red quartz and as to the place or locality in which it was found. Accordingly the other members of the original expeditions had no interest in the mining property.

McGahey v. Oregon King Mining Co., 165 Fed. 86, Nov., '08.

ASSIGNMENT OF OIL LEASE.

Trustees appointed in proceedings to dissolve a corporation cannot bind the corporation by an assignment by them as such of a lease to drill an oil well by covenanting that they had good and lawful authority to make such assignment, but where such assignment was made without covenants of warranty.

Shannon v. Mastin, (Mo. App.) 114 Southwest, 1127, Jan. '09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

MINING LAWS OF IDAHO. Compiled by F. Cushing Moore, State Inspector of Mines. 8vo., pp. 30. 1909.

Commercial Paragraphs.

THE WOOD DRILL WORKS, of Paterson, N. J., has a number of copies of an enlarged sectional cut of the Wood rock drill which it is distributing gratuitously among mining schools.

FALKENBURG & LAUCKS, assayers and metallurgists at Seattle, Washington, have moved their office and laboratory to First avenue and Yesler way, where they have excellent quarters.

THE CYCLONE DRILL CO., Orrville, Ohio, advises that W. H. Rukenbrod, who for the last twelve years has been connected with the Standard Oil Co., is now affiliated with the Cyclone Drill Company.

THE FOOS GAS ENGINE CO., Springfield, Ohio, advises us that the city of Bellevue, Iowa, has recently ordered a Foos three-cylinder, vertical engine, with gas producer, to replace a steam engine in the city electric light plant.

THE SULLIVAN MACHINERY CO. has moved its San Francisco office from 26 Fremont street to 461 Market street. Sullivan air compressors, diamond drills, rock drills, and other mining machinery are carried in stock at this office.

A contract has just been signed between the Joshua Hendy Iron Works and the Trinity River Mining Co., to furnish a complete hydro-power pumping plant, elevators, giants, pipeline, etc., for the company's mines near Lewiston, Trinity county, California.

THE HUNT FILTER CO., San Francisco, advises us that it has recently sold a standard 50-ton Hunt filter to the National Mining & Leasing Co., of Spokane, Wash. The machine will be used on the property of that company, 17 miles from Sumpter, Oregon. The offices of the Hunt Filter Co. have been moved to 518 California street.

Catalogues Received.

THE INTERNATIONAL STEAM PUMP CO., New York, has just published three new bulletins covering volute centrifugal pumps, triplex house tank pumps, and boiler feed pumps.

THE AMERICAN SPIRAL PIPE WORKS, Chicago, has just issued an attractive circular illustrating the adaptability of Taylor's spiral riveted pipe for mining and power purposes.

EDITORIAL.

MULE-BACK transportation figures prominently on another page of this issue. Messrs. Roberts and Bradley present a subject that is not new, but just because it is so old there is reason to revive it. The conditions of modern metallurgical work impose new burdens on the patient mule; he has to stagger under loads that grow heavier from year to year.

CHINA has no charms for Mr. John Hays Hammond. He declines the Pekin Embassy with thanks. He is done with pioneering, so he avers. That must send shivers down the backs of the Mandarins. But Mr. Hammond has missed the opportunity of his life; no such refinements of complot were possible in South Africa as would furnish scope for his genius in the land of the Dragon.

CONTRACT work on engineering structures calls for high technical skill, and the line between engineer and contractor in places is dim. There is value, however, in maintaining the distinction, and an excellent means of doing this, and at the same time of adding dignity to contracting itself, has been found in the formation of the American Society of Engineering Contractors. It starts with a large membership and high ideals.

TWENTY years ago the probability of the growth of gold nuggets in placers furnished a theme for active discussion. Finally the 'nays' had it, and a long silence followed. But the question is now revived by Mr. F. Lynwood Garrison, and a fresh discussion of this interesting topic will ensue. Perhaps the most significant point brought out is the growing fineness of placer-gold with increasing distance from its origin. If silver be actually eliminated from the alloy, the gold grains should show greater fineness on the periphery than within. The question is worthy of re-investigation by the new generation of geologists and chemists.

NO IMPROVEMENT in metallurgy within recent years is comparable to the invention of the dry-blast by James Gayley. The Franklin Institute has honored itself by according him the Elliott Cresson medal, while Mr. Gayley has only added an ornament to the distinction of masterful achievement. The contribution to the world's economy by the efforts of this accomplished scientist consisted in showing how to do practically what other blast-furnace managers had for decades sought in vain to do. This was to squeeze out the moisture by refrigeration, and to remove it from the blast after condensation. The merit of his achievement lies in its accuracy, the moisture being eliminated so that the air contains no more than should remain at the vapor tension corresponding to the temperature of refrige-

ration. The Gayley process has cheapened pig iron \$1 per ton. That effects a saving of \$20,000,000 per annum for the United States alone.

POWELL'S name will always be associated with the Grand Canyon, and it is fitting that a monument to him is to be erected on the edge of the great chasm which he explored. The appropriation made by Congress for this purpose has naturally suggested the desirability of a suitable monument over his unmarked grave in the Arlington National Cemetery. A committee consisting of Messrs. W. H. Holmes, H. C. Rizer, and C. D. Walcott has undertaken to raise funds for this purpose, and subscriptions may be sent to Colonel Rizer, in care of the Geological Survey at Washington. J. W. Powell was an influential factor in the development of the West, and deserves grateful recollection by his countrymen. Many will doubtless be glad of the opportunity to contribute.

THE TWENTIETH annual session of the Trans-Mississippi Commercial Congress will meet at Denver, Colorado, August 16 to 21. This body is one of the most influential of those which yearly meet to discuss commercial conditions and public affairs. It is more nearly national in scope and character than its name indicates, but the problems of the West are always its main concern. This year the national defense, particularly of the Pacific Coast, the development of a merchant marine, and various questions relating to the public domain, are on the program. With Mr. Thos. F. Walsh as president, mining matters are sure to have a place, though these will naturally be discussed in greater fullness at the American Mining Congress at Goldfield, Nevada, August 11 to 16. These annual conferences occupy an important place in the machinery whereby American public opinion is formed and expressed—and it is public opinion that rules.

MINING ENGINEERS are coming more and more to be mine managers. There is less disposition than formerly to consider the engineer as merely the source of technical information to be tapped off and used as needed by a business head. The executive control of most large mining enterprises is now in the hands of men of technical training. Skill in management, that rare sense of when and how to compromise, of how to read and to lead men, is becoming as necessary to an engineer as a knowledge of chemistry and physics. It makes and breaks companies and establishes and shatters reputations. Just how much depends on the mine and how much on its handling is not always easily measured. At one property where about 250,000 tons per annum are mined, the directors found not long ago the profits falling off and costs mounting. For a six-month period the average cost was \$3.49 per ton, the progress being steadily upward and ending with \$4.21. A change in management was made. For the ensuing six months, without damage to the property, the costs were brought down to an average of \$2.58, and the following year reached \$2 per ton. The mine was the same, the men unchanged, the treatment was

unaltered, and the market was against the second man, but he knew how to weld his force into a single unit and direct it steadily against the work to be done. In this case good management was worth approximately a quarter of a million dollars a year.

MERRY WIDOW hats have much to answer for, and virtue has been supposed to be found under the simple sun-bonnets of our fore-mothers. Millinery is, however, an economic adjunct to successful mining, at least in the South. When the Tennessee Copper Company put in converters there was great difficulty in keeping men steadily at work. In three days they earned enough to meet their simple wants, so why should they work six or seven—especially if certain of the days were cold and dreary? At such times the temptation to smoke by the fireside was almost fatal to steady running of the plant. Appeals to the men produced but little result, and a campaign of education was clearly necessary. Enter the Merry Widow. Wives of the staff dressed their best. Attractive displays were made in the stores. Wives of the men gazed and wondered. A necessity was created which resulted in a demand. To meet it six days' work became necessary to husbands and would-be heads of households. Poke bonnets are seen no longer in Ducktown, and who shall say that the dividends of this prosperous company may not be traced to the primeval love of woman for millinery.

FIRE has again scorched the Geological Survey at Washington. For the third time in six years, and for a second in as many months, the immensely valuable records of this branch of the Government Service have been barely saved from destruction. Following the blaze of last December, the House Committee on Appropriations proposed a suitable fire-proof structure for the Survey and related Bureaus. This, being subject to a point of order, was defeated by Mr. James R. Mann of Chicago, who refused the necessary unanimous consent. His reasons, as given in the *Congressional Record*, were the acme of cynicism. In effect, he excused his action by stating that sometime earlier Congress, yielding to popular demand, had gone so far as to purchase a site for a Hall of Records, and that thereupon the popular demand had subsided without insisting on the building. The implication was that if Congress would only stand firm and unafraid, the demand for a building for the Geological Survey would likewise subside. Possibly this experienced observer of public affairs is right, but one may wish, at least, that public business be conducted on a more rational basis than of alternately resisting and yielding to clamor. Every mining district in the United States has a direct interest in seeing that the notes and unfinished work of the Geological Survey be protected from fire. The records could not be replaced, and the incomplete work would cost time and much money to reproduce. In many cases the maps have been partly paid for by direct appropriation by the States, and no insurance is carried. The interest on the money invested in a building would amount to less than the rent now being paid. It is certainly a peculiar mental attitude which leads a Congressman

to obstruct a plain business move merely until he shall be hammered by letters and telegrams. Mr. Mann has been right on too many questions to permit such an attitude to go unexplained. If he has better reasons we would be glad to know them.

Mine Inspection and Geological Surveys.

Mine inspection has not generally been a function of geological surveys in America. In a few States the two services are joined, and for the last few years the mine inspectors in the Territories have been to some extent under the direction of the Technological Branch of the United States Geological Survey. In the main, however, the position of mine inspector has been more or less frankly recognized to be in politics, and political affiliations have been given more weight than technical skill in appointments. Despite the large and increasing number of technical graduates, and the importance to the industry of having well trained men, not many inspectors are graduates of schools of mines. There are better reasons for this than at first appear.

The mine inspector is primarily an officer charged with the duty of enforcing the law. In most States he has very little discretion and must take the law as it is and apply it to the particular facts before him. This requires sound judgment rather than refined technical skill. To bring men to accept his decisions and to obey his orders without constant friction, places a premium on leadership in preference to book-knowledge. Furthermore the inspector must have the confidence of the working men, since the time has gone past when his main trouble was with the operator. Companies have too much at stake and their officers are too well informed, to take any unwise chances. With the men it is different. Many of them are ignorant and foreign to our ways of thought. They do not see far into the future, and a conscientious inspector has before him the task of bringing them to accept rules necessary to their own safety. It is this which has made our politically chosen inspectors so generally successful; for as a matter of fact mine-inspection service in America, with all its admitted defects, is far from being as badly conducted as critics would have us believe. Under a system of political appointments the inspector is almost certainly a man who is, or has been, a miner; he therefore thoroughly understands and appreciates the miner's point of view. Furthermore, he is a leader, for men do not rise in politics without the gift of influencing men. Given good laws and such material, and an excellent inspection-service is made possible. This is not saying that it has always been realized. The modern political party is a chain of obligations, and officers owing their position to political favor are by no means always free or fearless.

Where mine inspectors are subordinate to the State Geologist, it results in the latter and the whole geological survey being forced into politics. A service which demands first of all the detached impersonal point of view of a technical investigator, must then take into account the times and seasons in announcing results, if not indeed in reaching them. This is

bad for the Geological Survey, and it is by no means certain that the inspection is improved. This may be fairly said without any disparagement of geologists, official or otherwise. Geological investigations and mine-inspection call for such different training and experience, and such diverse mental attitudes that a man may well succeed in one and fail in the other. It is true that Mr. C. J. Norwood, in Kentucky, does well in both, and that there are other exceptions, which, as usual, but serve to prove the rule. In Indiana the State Geologist, who appoints the inspectors, is nominated on a party ticket, pays political contributions, and the office is a part of the political spoil. That Mr. W. S. Blatchley has done good work, has been in spite of the system and not because of it. He has succeeded in getting rid of the appointment of oil inspectors, and possibly in time the Geological Survey there, as in other States, will be made non-political.

Mr. Herbert S. Hadley, the brilliant and militant Governor of Missouri, last winter recommended that the appointment of State mine inspectors be placed in the hands of the State Geological Board. He showed his good faith by making appointments subject to approval of that Board in case his recommendation was adopted by the Legislature. That the inspection-service in Missouri is capable of considerable improvement may be readily granted. Whether his recommendation was the only or the best way of meeting the difficulty is not so certain. If better inspection is really wanted it would seem necessary to appoint better men and to raise the pay so as to keep them, and to build up a strong public opinion favorable to good service. In the long run a State gets the kind of service in mine-inspection, as in other things, that public opinion demands, and appointing inspectors through a commission instead of directly, is only valuable as a declaration of policy, especially in Missouri, where the Geological Board can be, and in the past has been, dominated by a Governor wishing to make all appointments on a political basis.

The immediate effect of the Governor's recommendation has been to make trouble for the State Geologist. He is accused of having attempted to capture the inspection-service. Under cover of this criticism disappointed boomers of worthless enterprises, and speculators in land of uncertain value, are making a fight against the Survey. It should not succeed, for, despite all the vicissitudes through which the Geological Survey of Missouri has gone, it has done much excellent work and deserves support. More than all else it needs continuity of plan and effort, and the present Director should be given a reasonable opportunity to carry out his plans.

As to the larger question of the control of mine-inspection service, there are obviously two sides. Politics should not be allowed to interfere in the work of the office, but to hold that a man can not be a politician and yet an efficient officer and a good citizen would be to despair of American institutions. What we need is not to take places out of politics, but to change the character of party management and to educate public opinion as to what 'political obligation' may consistently involve.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. J. SPEAK is in West Africa.

H. C. BEELER is in San Francisco.

D. C. JACKLING is at Los Angeles.

E. M. McCORMICK is at New York.

W. H. SHOCKLEY has gone to London.

JAMES F. CALLBREATH is at Washington.

HOWARD DU BOIS is in British Columbia.

D. M. MONRO is enjoying a holiday in Scotland.

H. KILBURN SCOTT, of London, is in Nova Scotia.

U. S. GRANT sails for Valdez, from Seattle, June 8.

G. W. TRAEER has been at Pittsburg, Pennsylvania.

R. M. TOBIN, of the Kleinfontein Mines, is at London.

ROBERT SYSON has returned to London from Australia.

J. MORGAN CLEMENTS was at Cananea, Mexico, recently.

W. A. SCOTT sailed from Seattle for Ketchikan, May 21.

EDGAR RICKARD sails for London from New York, May 29.

F. LYNWOOD GARRISON will go to Silverton, Colorado, in June.

FRANK MERRICKS has left London for Nova Scotia and Mexico.

S. F. EMMONS has returned to Washington from Cobalt, Ontario.

CARNEY HARTLEY is examining placers in northwestern Colorado.

R. GILMAN BROWN is in West Africa. He is expected at London June 10.

HERBERT LANG has returned to Oakland from Mariposa county, California.

CARL A. ALLEN has returned to Denver from the Black Hills, South Dakota.

T. A. RICKARD has been at Washington and Philadelphia, on his way to London.

HENRY P. LOWE, of the Frontenac mine, Gilpin county, Colorado, has gone to London.

HEINRICH RIES will report on the clays of the Dominion for the Canadian Government.

P. S. INSKIP is inspecting the properties of the British South Africa Co., in Rhodesia.

VICTOR RAKOWSKY, of Duluth, Minn., is superintending concentrating tests at Dallas, Texas.

ALEXANDER E. OUTERBRIDGE, Jr., has returned from Jamaica, to Philadelphia, Pennsylvania.

H. B. PRICE, recently manager of the Crown Reef, has joined the staff of the Rand Mines, Ltd.

L. M. LOUIS is superintendent for the Round Mountain Mining Co., at Round Mountain, Nevada.

W. ROWLAND COX is examining mines in northern Mexico for the A. S. & R. Co. and other interests.

A. J. BRETT, formerly manager for the Treasury G. M. Co., is assistant manager of the Crown Mines.

T. KERR, recently manager of the Jumpers mine, has assumed the management of the Benoni Consolidated.

C. COLCOCK JONES is examining placer properties at Manhattan, Nevada, in the interest of Los Angeles clients.

W. W. LEACH, of the Canadian Geological Survey, has gone to the Skeena River district, in British Columbia.

BEN. B. LAWRENCE has returned to New York from a periodical visit to the Kerr Lake mine, at Cobalt, Ontario.

JOHN HAYS HAMMOND delivered the commencement address at the School of Mines, Golden, Colorado, May 28.

A. W. G. WILSON has accepted an appointment with the Mines Branch of the Department of Mines, Ottawa, Canada.

J. C. VIVIAN, of the Rio Tinto Mines, has been appointed underground manager of the Great Boulder Perseverance, at Kalgoorlie, Western Australia.

General Mining News.

ARIZONA.

COCHISE COUNTY.

A dividend of 50c. per share was declared by the Old Dominion Copper Co.—A cross-cut on the Superior & Boston property has struck ore running 14% copper. The raise from the drift on the 400-ft. level has cut the old shaft which is now being re-timbered. Frank H. Probert is consulting engineer.—Two more furnaces have been blown in by the Copper Queen. This will make a total of nine, each with a capacity of 500 tons.

GILA COUNTY.

Much development work has been laid out on the properties of the Cordova and Live Oak Copper companies. On the Live Oak property the shaft will be sunk to the adit level and a drift run to connect them.—Sinking from the 1200-ft. level of the Gem shaft of the Globe Consolidated will start within a few days.—All the openings at the Inspiration Copper Co.'s property near Globe are in ore. The showing at the Joe Bush shaft is excellent, as sulphide ore has been struck, assaying 2.9% copper. It is believed that the mine may be worked by steam-shovels, and that copper will be produced at 8c. per pound.—The Arizona Commercial Co. is making good progress with construction work. The concrete foundations for the hoist, head-frame, and power-house have been completed, and the company is starting work on the foundation for the furnace-building; much of the machinery and structural steel is on the ground. Underground work has been delayed somewhat by the heavy flow of water, which, however, has ceased to give concern, as ample provisions have been made to handle it.

MARICOPA COUNTY.

The Esperanza group of eight claims situated three miles east of the Harqua Hala mine has been purchased by R. V. LeGrand for Pasadena capitalists.—A shaft is down 63 ft. and a core-drill is being used to prospect the ground of the Alvin Development Co. of Houghton, Michigan.—Several carload lots of ore have been shipped to the smelter at El Paso by the Arizona Bouse Copper Co. from their Little Butte mine. The ore is coming from the 115-ft. level, though the shaft is down 200 ft. J. C. Denton is superintendent.—The Ray Northern Copper Co., W. B. Twitchell president, has taken over the Mayflower group of 14 claims two miles north of Ray. A force of men will be put to work shortly. About 5000 ft. of work has been done on the Mayflower claims and the workings show some good grade copper ore. The formation is similar to that on most of the adjoining properties, and can be worked at comparatively small expense by the caving process.

CALIFORNIA.

MARIPOSA COUNTY.

James F. Peck, of San Francisco, one of the owners of the group of mines known as the Mose Rogers property, situated in the Quartzburg mining district, has bonded that property to New York capitalists and work has been started. Richard O'Brien, of Hornitos, is superintendent, and J. H. Shockley, of New York, the consulting engineer. Among this group are the Washington, Franklin, Jenny Lind, No. 9, Quartz Mountain, and Pool claims. These properties are equipped with machinery and hoisting plants. Power will be obtained from the Exchequer plant on the Merced river.

PLACER COUNTY.

The Begole Mines Syndicate of Boston has an option on the Annie Laurie and the Alameda mines, about seven miles from Colfax. They are developing each property by two adits, the lower on the Annie Laurie being about 700 ft. below the old workings near the top of the hill. Both adits are in quartz of milling grade. Power for the compressor is furnished by a Pelton wheel which is driven by a water column of 180 ft. head. The mine is equipped with an assay office, machine shop, and living houses.

SIERRA COUNTY.

(Special Correspondence).—A strong shoot of rich ore has been intersected at the El Dorado mine. The first blast uncovered ore running over \$80,000 per ton. The management reports the strike one of the richest ever made in the district. H. J. Johnston is owner.—The third shipment of ore from the Sixteen-to-One mine for May has been made to Nevada City. It was valued at \$125,000. The vein continues 30 in. wide and has been opened up in the main adit for a distance of 100 ft., with no indication of the end.—The adit at the Red Star is expected to intersect the Tightner vein within 100 ft. Good milling ore is coming from the main vein.—Sulphide ore assaying \$125 per pound has been uncovered at the Rainbow in the raise from the adit.—Colonel W. L. Stevenson and associates of New York have resumed work at the Gold Canyon and are arranging for vigorous developments.—Eastern interests are operating the Mammoth Springs mine and developing milling ore.—The new three-compartment shaft at the Alaska is down 500 ft. and a cross-cut is advancing from the bottom of the shaft to strike the vein about 100 ft. northeast of the old workings. The mine is equipped with a 20-stamp mill, electric pumps, hoist, and compressors. George St. John is superintendent.—As a result of the recent fitch strikes, Alleghany is booming. Outside capital is active and a large number of properties are receiving attention. Several cases of claim-jumping are reported.

Alleghany, May 24.

Lawrence N. Wagner has bonded the Minnie D. mine from Albert Holmes and is preparing to commence active work.—The West Point mine has been bonded for a San Francisco corporation by F. M. Phelps. It joins the White Bear and has the continuation of that channel.—John Costa, manager of the White Bear, drove an adit under the channel and raised to the gravel, which pans gold freely and is estimated to go \$5 to the car.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Forty men have been put to work at the Seven-Thirty mine by the new manager, J. H. Robeson. He intends to connect the shaft with the Phillips drift run from the Burleigh adit.—It is understood that work will be resumed in the breast of the Capital adit the first of the coming month. The bore is now in 5300 ft., and the heading is nearing the Sporting Times vein. The manager, W. M. Cooper, is adding to the working force as fast as conditions permit. In the raise being put up in the east drift on the Aetna vein a streak of ore is exposed that is 18 in. wide, and is said to assay 3 oz. gold, 18 oz. silver, and 40% lead. The capacity of the mill is to be increased by the addition of another 100-ton unit, in which, it is reported, the Malm process will be installed.—The raise being put through from the Scepter adit to connect with the Sunburst workings has progressed 110 ft., leaving only 260 ft. more to be driven. This will speedily be accomplished with the machine-drills lately installed by the superintendent, A. B. Montgomery.—Another contract is to be awarded for the advance of the Prudential adit, the portal of which is situated on Republican mountain. The bore is in over 750 ft., and from surveys another vein will be intersected within 25 or 30 ft. F. A. Maxwell is manager.—Shipments of ore from the holdings of the Waldorf Con. M. & M. Co. will be started next week, as by that time the Argentine Central railroad will be opened for traffic. There is now ready for delivery about 1500 tons of smelting ore worth from \$60 to \$70 per ton. It is understood that work will be started at once to re-build the concentrating plant and increase the capacity from 125 to 250 tons per day. Lumber will be taken to the seat of operations as soon as trains can reach the Wilcox adit. The machinery has already been ordered by E. J. Wilcox, the manager.

Georgetown, May 21.

GILPIN COUNTY.

Several loads of milling ores have been shipped from the Leontine mine on Quartz Hill to the Black Hawk stamp mills, for testing. The property is under lease and bond to

the German Gold & Uranium Mining Co., in which Pennsylvania capital is chiefly interested.—Gurley & Gunnell, of Denver, have taken a lease and bond on the Josephine property in Little Jenny Lind gulch, north of Apex.—Three carloads of concentrate from the Perigo mill were shipped from the Rollinsville depot of the Moffat road to the Argo smelters during the past week.—Malet & White, lessees at the Belcher mine on Quartz hill, have sunk the shaft 50 ft. this winter and are now down a distance of 180 ft., at which depth they have commenced to drift on a vein carrying gold and copper.

GUNNISON COUNTY.

The Irene group has lately been added to the Carter holdings at Ohio City. The bore already in a mile will be pushed 1000 ft. farther to undercut the Volunteer property.—An orebody was cut in the Lookout property south of Pitkin. The quartz is of good milling grade. J. P. Miller is the owner.—J. T. Bennett is starting work on the Mountain King mine above Gothic. A snowslide carried away the pipe-line that furnishes water-power.

TELLER COUNTY.

The Trilby Mines Co., James T. Stewart, general manager, has made heavy production since the first of the month, shipping from the Trilby mine on Bull hill to the valley plants. The ore has been graded, the content varying from about 1 to 2 oz. gold per ton. The company is mining ore in several levels of the main shaft, but the heaviest tonnage is made from the ore-shoot on the main Trilby vein under development at the twelfth level. At this level the ore is broken from 15 to 20 ft. wide. A station has also been cut at the thirteenth level.—A prospecting permit, with option of lease covering a two years' term, has been secured by the Furst brothers and McBird of Victor, on the main shaft and workings of the Last Dollar Gold Mining Co., on Bull hill. The parties have commenced examination work.

Operations have been resumed on block 27 on School Section 36, on the northern and western slopes of Grouse mountain by H. P. Reiton, holding a long-time lease from the State Land Board. At an approximate depth of 50 ft., a 3-ft. vein has been exposed in the phonolite, near the granite contact, and a drift is now being carried on this vein. The quartz is from 3 to 4 ft. wide and assays well.—Shipments have been resumed from the Blanche Gold Mining Co.'s Uncle Sam fractional claim containing about 2½ acres, adjoining the Acacia company's Morning Star mine. The property was recently leased to the Morris brothers of Cameron, who are also operating a lease on the Morning Star, and the vein recently opened up by cross-cut from the 100-ft. level of the Uncle Sam shaft is the northern extension of the Morning Star vein.

IDAHO.

NEZ PERCE COUNTY.

Mill tests of copper ore from the Bullion property near Lookout, made at the Coeur d'Alene Concentrating Co.'s plant, has given satisfactory results. A ton of ore was run over the vanners and tables, giving a clean concentrate, which has not yet been assayed, but previous tests showed it to assay 19% copper, or a gross value of \$38 per ton, from which must be deducted \$5 per ton for freight and treatment at the smelter at Tacoma, leaving a net value of \$33 per ton.—The Orofino Mining Co. has just made a strike of galena on the property. This has increased until the whole face of the drift is in ore. Arrangements for the handling of the ore are being made, and when completed shipments will be begun over the Idaho Northern.

SHOSHONE COUNTY.

A considerable impetus has been given to the whole mining industry of the western region of the Coeur d'Alene by the resumption of development in the property of the Vienna International mine which has been shut down for almost two years. Development at present is being confined to the upper levels. A splendid showing of both shipping and milling ore has been made in all the workings. Much of this ore is sorted out ready for shipment, several carloads having been taken out in the course of development.

Regular shipments will commence during the coming summer.—A big strike of ore has been made in the property of the Bear Top Mining Co. in the Murray district. The ore was exposed in the raise, being run from the No. 3 to the No. 2 levels. The full extent of the orebody has not yet been ascertained.—The first shipment of ore has been made from the property of the H. E. M. Mining Co. in the Revenue Gulch district. The ore has been sent to be tested at the sampler works of the Federal Milling & Smelting Co., after which it will go to the smelter at Tacoma. The showing in the mine continues to improve, and a large amount of galena and some native silver has been exposed in the upper drift.—Owing to labor troubles shipments of ore from the Caledonia mine in the Wardner region to the American Smelting & Refining plant at East Helena have ceased. The ore is now being sent to the Tacoma plant.—A strike of 18 in. of carbonate ore carrying about 25% galena has been made in the property of the Clear Grit Mining Co., near Delta. A small stringer was opened and drifted on for 30 ft., when it opened out to the width mentioned. The ore is improving as development progresses.—A wagon-road is being constructed to the property of the Midway Summit Mining Co., and as soon as this has been completed about \$2500 worth of machinery, including a compressor, will be installed. It is intended to drive a lower adit to work the ore showing in the upper workings.—Development is to be resumed at once on the property of the Tucker Mining Co. near Mullan, and a contract for 200 ft. has been let. It is believed that the main lead will be encountered in about 50 ft., when the balance of the contract will be taken out in drifting. The adit is now in about 700 ft.—Development at the property of the Copper King Mining Co. has again been hampered by a flow of water. This has now subsided enough to allow the men to resume. The adit level has been driven about 1300 ft. and progress at the rate of 8 or 9 ft. a day is being made. The adit, when completed, will be about 3000 ft. long.—The Snowstorm Mining Co. has disbursed a dividend of \$45,000 for the month of May. It is believed that regular dividends will be paid from now on.—A report from Burke states that the Day Brothers and associates are planning to drive a tunnel to open at depth the ore of the Hercules, Humming Bird, Ambergris, and Tamarack & Chesapeake mines. The tunnel will start from the end of the present Humming Bird tunnel, which has already been driven about 3000 ft. It is believed that 4000 ft. more will be sufficient to tap the Hercules and Ambergris orebodies, and 7000 ft. from that point will reach the Tamarack & Chesapeake property. All of the mines named are controlled by the Day Brothers. Such a tunnel would materially reduce the cost of shipments from all the mines as well as the cost of handling supplies, and at the same time allow an outlet for the ores right to the tracks of the Northern Pacific railroad.

MICHIGAN.

Isle Royale is gradually increasing its mining force, and now has 73 machine-drills in operation. About 45 of these machines are engaged in stoping in the No. 2 and 6 workings. Operations from the No. 4 and 5 shafts are confined to development work. The grade of ore in the new workings to the south averages about 25 lb. mineral per ton of rock, which compares with 18 to 20 lb. per ton from the older workings around the No. 2 shaft. At present there are two shafts equipped with permanent hoisting machinery, and a third, that at No. 4, will be similarly equipped within the next few weeks. The mill is working at about 50% of its capacity.—Operations at the Mohawk are confined to diamond-drilling, to determine the exact position and dip of the Kearsarge lode between the Mohawk No. 5 shaft and the Ahmeek No. 2. When this information is ascertained sinking can be begun, starting at a point about 800 ft. north of the Mohawk-Ahmeek boundary. The overburden at that point is 40 ft. deep.—The report of the Superior Copper Co. for the year ending April 30 shows that a profit of \$35,000 has been made, instead of a loss as in the previous year. Shipments to the Atlantic mill were started in January, and showed 22.2 lb. copper per ton crushed. The No. 1 shaft has been widened for two skip-

ways and re-timbered from the surface to the fifth level. The openings have shown good copper ore in No. 1 shaft and drift. This shaft is now below the eleventh level and the cross-cut has reached the vein.

The directors of the Calumet & Hecla have declared a quarterly dividend of \$6 per share. With the payment of this dividend stockholders will have received \$103,950,000 in dividends since the formation of the company.—The Oneco Copper Co. is planning to diamond-drill its property in an effort to find the Baltic lode, which was recently disclosed by trenching upon the lands of the New Baltic Co., and presumably strikes across the greater part of the Oneco tract. The work will be in charge of the local management of the Hancock Consolidated Co. Operations are expected to begin this month.—Calumet & Hecla is engaged in sinking a shaft on the White Pine property in the Porcupine Mountain district of Ontonagon county. The White Pine is the property of the St. Mary's Mineral Land Co. and is held under option by the Calumet & Hecla company.

MONTANA.

SILVER BOW COUNTY.

The fire and gas in the Anaconda, Neversweat, and St. Lawrence mines, which had its origin in the St. Lawrence in 1889, seems to be spreading. The Anaconda mine had to be shut down entirely last week, and the gas interfered with operations in the two adjoining properties—the Neversweat and the St. Lawrence. Frequently gas breaks out in unexpected places and instantly fills up the underground workings, driving out the miners and making work impossible. For several months miners have been engaged in bulkheading the workings surrounding the fire zone in the Anaconda mine, and when the bulkheads are finished it is hoped the smoke and fire question will be solved for some time to come, but mining may have to be abandoned in a large portion of the Anaconda mine.—The Amalgamated Copper Co. has decided to sink a new shaft at the Gagnon mine, the property of the Trenton Mining & Development Co. It is intended eventually to abandon the old incline shaft. Several hundred feet have recently been added to the old shaft, which is now 2300 ft. deep, and the lower openings have proved so satisfactory that the Gagnon will again be converted into a producing property.

NEVADA.

ESMERALDA COUNTY.

A new find has been made about 55 miles southwest of Goldfield in Cottonwood canyon in the north end of Death valley. Samples carrying silver, lead, and gold have been brought in.—The Kansas City Velvet lease is making small shipments. A drift has been run on the 50-ft. level, cutting an 18-in. vein that assays about \$6 per ton.—The McKinley-Hawkins lease at Rawhide has cut several veins of milling ore. Drifts are being started along the vein.

A new tube-mill has been ordered for the Florence mill. The mill is now treating from 145 to 150 tons daily, and this addition will increase the capacity about 30%. The cost of milling now is about \$4.25.—A new 75-hp. hoist and large head-frame has been installed at the Grizzly Bear mine. The shaft is now down 500 ft., and is still in the Clermont vein, passing through it on the dip. A large body of quartz has been cut.—One thousand feet of new cable has just been placed on the hoisting plant at the Stoneham-Moore lease on the Combination No. 2, and sinking from the 500-ft. level started.

LINCOLN COUNTY.

A shipment of 20 tons was made from the Spokane lease, at Searchlight, to the smelter at the Needles.—The Lenape Gold & Copper Mining Co. has completed new office and residence buildings, and head-frames over both shafts, which are down 175 and 115 ft.—The Searchlight-Combination has cut a 6-in. vein at the 65-ft. level. E. H. Hitchcock is superintendent.

NYE COUNTY.

Manhattan is doing well in the development of the placers discovered, which are proving very rich. The gravel chan-

nel is an old wash, largely clay, on bedrock in the main gulch, much like the placers of the small gulches in Idaho and Montana, and evidently formed by a considerable stream.—M. A. Nurse and associates of Sacramento and Goldfield have closed a contract with the Nevada-California Power Co. for a daily electrical energy of 100 hp. The first dredge, which is of the suction type, will have a 6-in. pipe with air and water down to bedrock. The company controls a number of claims in and around the town.—The citizens of Manhattan have organized a vigilance committee to protect holders against claim jumpers, who have been active recently.—The Sunrise Co., operating on the Wilson claim of Wolfstone Extension, is working three shifts of eight men and arranging for the installation of a complete placer plant. The channel has been opened for several feet, with values running from \$8 to \$15 per yard. Most of the gold is found near the northern rim.—The Chindren-Brown-Wilson lease is working a small body of gravel estimated to contain from \$700 to \$1000.—Cook & Kern have taken 300 ft. on the Black Cat and are arranging for extensive work.—Careful prospecting and testing of the placers at Manhattan and Central indicate that the average content is about \$10 per yard. Practically all require considerable capital for their working, and the camp is not a poor man's paradise.—Quartz mining is again assuming prominence.—Orders have been received from head-quarters to resume work at the Federal. The 200-ft. shaft will be carried to the 500-ft. level and comprehensive developments carried on. W. P. Wixon is superintendent.—The Irvine lease on Broncho creek has struck, at a depth of 6 ft., a 5-ft. vein assaying \$100 per ton. The ore carries much flake gold.—It is expected that the Tonopah Mining Co. will move its cyanide plant from Millers station to Tonopah, and thus cut off railroad transportation costs. A heavy flow of water at the 1300-ft. level of the Mizpah shaft assures plenty of water for milling operations.—A group of Eastern capitalists have secured the control of the Aurora Bullfrog Mining & Exploration Co., which owns 18 claims. The property is a large low-grade one, and the company contemplates the erection of a mill.

A new 300-hp. electric hoist has just been installed at the Mizpah shaft by the Tonopah Mining Co. and another compressor ordered. A cross-cut has been driven and a sump cut to catch the water coming down the shaft. A large station pump will be installed and the sinking below this point will be in dry ground.—The shaft of the MacNamara mine is down 770 ft. and a station has been cut. A few feet above the station the shaft cut a body of quartz lying on the contact between the dacite and underlying porphyry. On account of the vein lying very flat the station was cut about 20 ft. above the bottom of the shaft and a cross-cut commenced to tap the vein. This has been started, but has not yet encountered the quartz. A 5-ton shipment of sulphide ore was made from the Manhattan-Dexter. This will be tested by the Western Ore Purchasing Co.—The Solid Gold Mining & Leasing Co. has purchased the controlling interest in the Round Mountain Daisy Mining Co. This also includes the water-rights owned by the Daisy operators. The ground is adjoined on the east by the Fairview mine and on the west by the Antelope. A considerable amount of work has already been done and there are a number of orebodies of milling grade being developed.—The Fairview mill had its monthly clean-up a few days ago. This mill is treating 20 tons per day of ore which gives a gold return of \$15 to \$17 per ton. Only one shift is necessary in the mine to keep the mill supplied at its present capacity.

WHITE PINE COUNTY.

The April production of Nevada Consolidated and Cumberland-Ely was the highest in their history, and according to reports now at hand there will be still further increases at both mines during the current month. During the first week of May the output of the Nevada Consolidated averaged 58 cars, and the Cumberland-Ely 32 cars per day, or a total of 5000 tons daily. At the Nevada Consolidated overburden is being removed at the rate of 180,000 tons per month. Another steam-shovel has been ordered, with the

aid of which it is expected to remove 250,000 tons of overburden per month. During the month of April close to two million tons of ore were developed, and it is now stated that more than 30,000,000 tons of commercial ore is blocked out in the property.

OREGON.

BAKER COUNTY.

The South Pole mine at Sumpter has cross-cut an excellent body of ore. The ore is free-milling and the 5-stamp mill on the property will soon be started. Andrew Hansen is the owner.

JOSEPHINE COUNTY.

I. K. Evans, of Philadelphia, has purchased, on behalf of a syndicate, at a sheriff's sale all the holdings of the Galice Hydraulic Mining Co., St. Helen's Hydraulic Mining Co., the Galice Consolidated mines, and the T. K. Anderson properties. These corporations became involved in litigation over the right to use the waters of Galice creek. The Philadelphia syndicate will organize a corporation to be known as the Galice Placer Mines Co., and under this name the work of mining will be carried on.—Ore has been cut on the lowest level in the Alameda mine. This now exposes ore on four levels. E. R. Crouch is foreman.

WASHINGTON.

FERRY COUNTY.

The lessees of the Lone Pine claim, of the Pearl Consolidated group, are driving from the north end adit, to intercept the No. 4 Lone Pine vein, which yielded some ore of more than ordinary richness in the upper workings. Eleven men are employed. A 3-hp. gasoline engine has been installed, to run a fan for ventilation.—Two cars of ore were shipped from the Lucille Dreyfus mine, near Danville. In future one carload of ore per week will be shipped.—A large tonnage of ore has been blocked out in the Lone Star and Washington mines. The Canadian Pacific Railway Co. is building into Wellington camp, just across the international boundary line, in British Columbia, and will continue to a point opposite the Lone Star claim, from which an aerial tramway will be constructed to convey the ore to the railway, for shipment to the smelter.—D. Quincy Adams Mills, manager for the Little Pittsburg Mining Co., in the Republic district, reports he has found a body of gold and copper ore on the property in extending an old adit driven some years ago. The extent of the find is not known, as it has been cross-cut only three feet. The quartz shows a ribbon structure.

JEFFERSON COUNTY.

(Special Correspondence).—The Irondale Steel Co., at the head of which is James A. Moore, of Seattle, has a 100-ton blast-furnace at Irondale, 6 miles south of Port Townsend. The company is building two open-hearth steel furnaces and will install rolling mills. Henry S. Moulds, of Pittsburg, is connected with the Irondale project in a consulting capacity, and states that within six months from now the company expects to be producing 150 tons of steel daily. The company for two years has been developing iron mines on Vancouver island, near Quatsino bay, from which the necessary supply of iron ore is to come. This is a soft hematite ore and an immense tonnage of it is said to be accessible. It is proposed to obtain coke from Pierce county, this State, where mines of coking coal have been under development for some time.

STEVENS COUNTY.

D. C. Corbin is reported to have bonded the Wagner group of claims, situated on Hall creek, a tributary of Duncan river. The stamp-mill and concentrator on the Easter Sunday mine is completed.—Capt. L. Beecher has secured the right for the Hess cyanide process for Stevens and Ferry counties, and will erect a 5-ton experimental mill in Orient district, for the Border Mining & Milling Co., to treat ore from a number of claims taken over and bonded by the company. A valuable strike of ore has been made in the Cuban mine on Kettle river. The adit on the North Star mine has 200 ft. farther to run before completion. Ore

of good grade is still being found in the shaft, in sinking on the Second Thought vein.—The First Thought mine has been shut down, presumably on account of the closing of the Greenwood smelter, and work may possibly not be resumed until the company builds a cyanide mill.—The shaft on the Kettle River mine, at Rockcut, is down 70 ft. and the bottom is in ore, carrying gold, silver, lead, and copper. A steam-hoist and pump has been installed. The shaft will be sunk to the 100-ft. level, where a station will be cut.—The Ark Group Mining Co. has broken into a body of gray copper ore, in a cross-cut being driven to reach the main vein, at a depth of about 200 feet.

CANADA.

BRITISH COLUMBIA.

An extensive plan of development work is outlined for the Westmount mine. F. E. Griffiths, manager and part owner, has just returned from eastern Canada, where he has conferred with associates in regard to the work, and development will be started immediately in No. 3 tunnel.—It is said that work is to be resumed on the Mohican group controlled by the Poplar Creek Gold Mines Co. There is a good body of concentrating ore in the workings of this property, but only nine tons have been shipped to date, railway facilities being lacking. From the shipments made 60 oz. silver and 30% lead per ton was received.—The Majestic group of claims, at Sandon, has been bonded by G. H. Wright, of Vancouver, and a crew of 10 men will be put to work on the property at once. On the Morning Star group, Lardeau, ore has been cut that assays 2.2 oz. gold, 713 oz. silver, and 5.8% copper. The property is looking quite promising as work proceeds.

The Snowshoe mine at Phoenix continues to ship 10,000 tons of ore per month to the Trail smelter, where it is valuable as a flux. This ore is all being taken from above the adit, as the mine has not been unwatered below this level, and will not be until heavier shipments are necessary, as there is an ample tonnage of good ore for present requirements in the upper workings of the mine.—The British Columbia Copper Co. has 75,000 tons of ore ready to ship from the Jackpot mine, at Wellington, and about 200,000 tons ready for stoping from the No. 7 in Central, while the Lone Star is shipping steadily. With this spur line finished and shipping in progress the outlook for profitable operation at the Greenwood smelter of this company is favorable.—The Sally and the Golden Eagle mines both appear again on the shipping list for the week ending May 15, with 16 and 60 tons respectively.—The Greenwood tunnel has now advanced about 75 ft. and the work is progressing favorably. The operators are considering the installation of an 8-ft. Swiss-Chandler tunneling machine, which will drive the adit about 45 ft. per day. This will cost in the neighborhood of \$60,000, but would prove economical even at that figure. This tunnel will open about 16 claims in the upper workings of which high-grade gold-silver ore has been found. In some of the claims a depth of 2400 ft. will be obtained.—A good body of ore has been opened on the Florence claim near Hedley. This property is situated so that it can be worked advantageously and will only require a moderate amount of capital to place it on a shipping basis.—The production of the Le Roi No. 2, at Rossland, is averaging nearly 500 tons per week of good ore which is going to the Northport smelter. A find of rich ore has been made on the 400-ft. level of this mine in a 30° diamond-drill hole. From 101 to 104 ft. the core assayed 0.12 oz. gold and 1.4% copper; from 118 to 119 ft. 9 in., and 6 in. at 121 ft. returned 1 oz. gold and 2.3% copper, while the sparsely mineralized portion of the core from 119 ft. 9 in. to 121 ft. ran 1 oz. gold and 1.4% copper.—A new shoot of ore has been opened up in the Centre Star mine that will average over \$24 per ton. Considerable ore is being taken from the shoot on the fourth level of the Idaho and from the workings of the Iron Mask.

The owners of the Red Cliff copper-gold group on Portland Canal will expend about \$25,000 in development work this summer and have already sent a small force of miners to the property. The main orebody is about 100 ft. wide.

and an average assay taken near the Montrose claim yielded \$25 in gold, 3.3% copper, and 4 oz. silver per ton. There is a short tunnel in ore on the property, and this will be continued for some time to come.—The work which Herman Beckman has been doing on the Kimberley group of claims at Kamloops has disclosed a large body of low-grade ore. Most of the work on the group has consisted of open-cuts and stripping, and this has opened up a mineral zone about 1000 ft. wide by over 3000 ft. long. This ore will carry over 2% copper and \$1.50 to \$6 in gold, as well as a high percentage of iron. Lenticular bodies of ore of higher grade are cut in the course of the work. There is limestone on the property and as the ore can be quarried there is little doubt but that it could be treated profitably by a smelter at Kamloops.

ONTARIO.

The Crown Reserve is drifting on the 200-ft. level, the deepest on the property. The vein runs from 6 to 8 in. wide

Map Showing Position of Cobalt and New Districts in Ontario.

of high-grade ore. During April the Nipissing mined ore of an estimated net value of \$149,739. Of the total 291,626 oz. of silver produced during the month, 108,680 oz., or 37%, came from the Kendall vein. The yield of the Kerr Lake during April was about 200,000 oz. silver, produced from 84 tons of ore. Most of this came from No. 7 workings, which include the recent discovery known as the McDonald vein. On this vein a winze has been sunk 32 ft. from the 150-ft. level, the ore extracted averaging 2000 oz. per ton. The pay-shoot on No. 7 has been traced for 600 ft. A new vein was recently struck about 4 ft. from the main vein on the Peterson Lake lease of the Little Nipissing. It is over 16 in. wide and carries 2 in. of cobalt. A new hoist and boiler are being installed on the company's J. B. 2 property, where drifting will be carried on at the 125 ft. level on a cobalt vein, with fair silver content. The Right of Way has de-

clared a bonus of 10% payable May 20.—A 10-in. vein that assays as high as 3184 oz. silver has been cut in the Beaver Consolidated mine. The vein has been found only after persistent prospecting, as something over 3000 ft. of development has been run.—The Big Pete and King Edward mines both shipped a carload of high-grade and concentrate to the smelter.

MEXICO.

CHIHUAHUA.

The American Smelting & Refining Co. has decided to add at least two new furnaces to its Chihuahua smelter. The plans are said to be about completed. These furnaces are expected to be in commission by the end of the year. The local smelter now has three furnaces with places for two more. The present capacity is 450 tons daily, and two new furnaces will increase it to 750 tons per day. The local smelter is now taxed to its utmost capacity. The A. S. & R. Co. has one aerial tramway in Santa Eulalia and is about to begin another.

GUANAJUATO.

H. W. Benton, general manager for the American Mining & Milling Co., of the Corwin-Green interests, has just completed his annual report which has been submitted to the board of directors. The amount of development work accomplished at El Roble since November 3, 1908, is 303 metres, or approximately 1000 ft. This was in drifts, cross-cuts, and raises. One of the raises connects the lower workings in the El Roble with the old Spanish workings. Considerable water has been encountered in No. 3 drift, which is being drilled to tap the extreme lower levels of the antigua workings.—The general manager of the Guanajuato Consolidated Mining & Milling Co. reports the return for the month of April 1909 as follows: The mill ran 28½ days and crushed 6984 tons of dry ore; concentrate shipped to smelter, 148 tons; estimated realizable value of bullion produced, ₡56,600; estimated value of concentrate, ₡46,600; total gross value in products, ₡103,200; less working expenses, including marketing of bullion and freight and treatment charges on concentrate shipped to smelter, ₡69,500; estimated profit, ₡33,700. Of this, ₡11,000 has been expended on development account. Amount of development work done, 406 feet.

SONORA.

The Greene-Canaana properties are producing copper at the rate of 50,000,000 lb. per year, and no effort will be made to increase this output at the present time. The copper content of the ore is now averaging between 45 and 50 lb. per ton. Remodeling the old plant is having a beneficial effect of the cost of operations, but this cost is still as high as 10c. per pound laid down in New York. The Capote mine, which was closed down for some time on account of a fire underground, is now contributing 10,000 tons of ore per month to the total output. By the first of June the company expects to put into commission its new compressor, which will supply air for all the mines, and effect a saving of \$5000 per month as compared with present costs. A new central electric lighting plant is also nearing completion. —Four carloads of new mining machinery have been shipped to the Zambona mines, at Minas Nuevas, where arrangements for its installation have been completed. The management of the Zambona Development Co. expects to have the new cyanide plant and other machinery installed and in operation within the next six months. A. J. Yaeger is general manager. —J. G. Alexander, who is now working the San Pedro mine under lease from the Moctezuma Copper Co., is starting a system of sub-leases. High-grade ore has been opened up in three places in the old working tunnel. In the Nacozari Consolidated Copper Co.'s main working tunnel on the La Galera claim, work is progressing satisfactorily, and the contact should be cut within 30 days.

C. B. Dunster has been examining the Promontorio mine, below Moctezuma, for Michigan parties. —W. P. Belding of Los Angeles has taken over from George F. Woodward and associates of Moctezuma the Pura Plata mine, lying about 15 miles west of Moctezuma, on a \$30,000 bond, and will start work immediately.

Special Correspondence.

LONDON.

Golden Horseshoe —Sons of Gwalia.—The Greatest Gold Mine.

The Golden Horseshoe mine in West Australia is a remarkably regular producer, and promises to continue so for some time to come. The results for 1908 were almost identical with those of the previous year. The ore crushed was 247,740 long tons in 1908 and 247,020 in 1907. The corresponding figures for the production were 145,363 fine ounces and 147,680. Similar figures for working expenses were £292,098 and £294,220. Owing to rather greater expenditure on machinery, the dividend distributed in 1908 was £240,000, as compared with £255,000 in 1907. The similarity in figures extends to the ore reserves, which on December 31 were 1,065,409 long tons, averaging 11.88 dwt., as compared with 1,602,332 long tons averaging 12.24 a year before. The mine has now been producing for 11 years and has yielded 1,604,028 fine ounces and paid £2,760,000 in dividends. The new machinery referred to consists chiefly of electric plant driven by steam turbines and a 1000-hp. air-compressor. Additional Wilfley tables have been provided for the purpose of removing the pyrite from the slime. It is interesting to note that the whole of the cost of mine development and plant has been written off out of profits, the amount of the mine development being £290,958 and of plant £485,329, so that these two items do not appear in the balance sheet.

Another of the West Australian mines, the Sons of Gwalia, is not making such large profits as four or more years ago, but recent discoveries promise to increase the yield. During the year 1908, the ore crushed amounted to 156,267 short tons and the yield by amalgamation and cyaniding was 54,915 fine ounces, an extraction of 29s. 9d. per ton. The total costs at the mine were 20s. 4d., of which 8s. 7d. was for mining, 4s. 6d. for development, 5s. 10d. for treatment, and 1s. 6d. for general expenses. The amount realized by the sale of gold was £233,340, and the total expenses, including depreciation, taxes, and London office, approximately £175,000. Out of the profits £40,625 has been distributed as dividends. In 1904 and 1905 the distribution was £105,000 per year. The exploration work undertaken recently has brought to light two bodies of high-grade ore, and at other parts the mine-ore of the present average grade is opening up well. The ore reserves have been considerably increased lately and now stand at about three years' supply, so that the prospects of the mine have substantially improved.

During the last few months there has been some agitation in financial circles for a law requiring bankers to publish lists of dormant balances and companies to issue similar returns of unclaimed dividends. There can hardly be doubt that deaths and removals provide companies and bankers with substantial amounts of unclaimed funds which usually go into the reserve. This topic is not exactly one for general discussion in a mining paper, and I only mention it because some of the South African companies make it a practice to publish lists of outstanding checks for dividends that have not been presented. For instance, the Robinson Gold Mining Co. has just published a list of 49 checks still standing. It may be argued that if the shareholders or their representatives do not look out for their dividends they will be no more likely to see the published list. On the other hand, some other reader of the list may identify a name as that of a friend, and so be able to draw his attention to it. Anyhow the companies which pursue this policy are to be commended for the additional consideration for their shareholders.

The discussion which occasionally crops up as to which is the greatest of gold mines is always interesting. Not past, present, or future yields and profits determine the point, but a combination of all. For instance, compare the Waihi in New Zealand with the Robinson on the Rand. The South African engineer would have some justification for claiming that the Rand, being a continuous deposit, should be reckoned as one mine, worked in independent sections;

but let that pass. The being found in the shaft, in sinking 315,111 fine ounces, value vein.—The First Thought mine crushed, and £825,000 was umably on account of the closing the commencement of oper and work may possibly not be milled has been 3,611,999 tons, builds a cyanide mill.—valued at £12,082,267, and the mine, at Rockcut, is down ore reserves on December 31 last cōrrying gold, silver, lead, of low-grade ore on the Main Reef ayp has been installed. ton, and 2,788,362 tons averaging 11.3 dwtel, where a station Leader and South Reef. Most of the ore no, has broken into from the two latter sources, and provision is being driven to dealing with the low-grade Main Reef ores by th of 40 new stamps, thus bringing the capacity up stamps. The working costs at the Robinson have greatly reduced lately and stand at the remarkably ic figure of 12s. 6d. per ton. This reduction has increased the profit in spite of falling contents, and has made it possible to treat the low-grade ores of the Main Reef. The life of the mine works out at about five years for the richer ores of the Main Reef Leader and the South Reef. It is too early to figure out exactly the life of the low-grade ores of the Main Reef.

Passing now to the Waihi, by way of comparison with the Robinson, since the commencement in 1890 to the end of 1908, the total ore crushed was 2,850,000 tons and the yield valued at £7,220,624, of which £3,825,386 has been distributed as dividends. During 1908 the ore crushed was 393,214 tons, and the realized yield in gold and silver £930,511. The contents are chiefly gold, the figures averaging 10 to 12 dwt. gold and 4 or 5 oz. silver. The dividend declared for 1908 absorbed £421,520. The ore reserves are given at 1,329,872 tons, and only include the ore that has been proved by drifts and cross-cuts. It is impossible to give an estimate of the life of the mine; all that can be said is that at many points there are large quantities of probable ore, and that exploration and development are continually adding to the reserves. So that though the Robinson is ahead as regards past and current history, the Waihi bids fair to win in the long run. The two mines have one point of similarity; that is, the managements are equally up to date.

SALT LAKE, UTAH.

Newhouse Mines.—International Smelter.—Iron Blossom Ore Trend.

E. P. Jennings has completed an inspection of the Newhouse properties in Beaver county. It is understood that he has been acting for bondholders. The impression is that his report will show a large tonnage of available ore. Samuel Newhouse says that work has been steadily carried on at the mine. The shaft, tunnels, and chutes have been re-timbered, and considerable ore blocked out. On the second level alone, 25,000 tons running above 3% in copper has been found. The character of the ore is changing with depth, though the value remains the same. Work on the mill is progressing satisfactorily. The new equipment includes 16 Callow tanks, 12 Wilfley tables, 4 jigs for treating tailing, a new system of water carriers, screens, and the MacQuisten tables for treating middling.

E. P. Mathewson, general manager for the International Smelting Co., has just returned from the Northwest. He has with him an expert botanist and a veterinarian, who will study the conditions of vegetation and animal life in Pine canyon. Six months after the smelter has been in operation, these men will return to the valley and will compare the conditions. This step is taken to determine whether or not any injury is done to life and property by the operation of the plant. While the smelting company has an option on all land that can possibly be affected by fumes from the stacks, precautions are being taken to prevent any possible litigation. The first steel for the smelter will arrive June 7; the track to the Tooele site will be completed June 1. It is now planned to have the smelter running not later than April 1, 1910.

The Iron Blossom vein, at Tintic, trends 5° west of south, according to John Roundy, superintendent. Various statements have been given out by visiting engineers, to the effect that the high-grade orebody was trending east. Prop-

and an average assay taken near the advantage of this to \$25 in gold, 3.3% copper, and 4 oz. of silver. The Government sets at rest all as the 'ore-hound' of the a short tunnel in ore on the property as the 'ore-hound' of the free dividend-payers in the tinued for some time to come.— Beckman has been doing on the

Most of the work on the **WASHINGTON.**

and stripping, and this **Reserve Lands. — Monument to Senator** 1000 ft. wide by over **War. — Coal Land Valuation.** 2% copper and \$.

percentage of iron from Joplin have been in Washington, pre- are cut in half for a tariff of one cent per pound on zinc in on the consideration of the matter has been postponed. little a spirited and acrimonious debate of four days the Senate fixed the lead schedule at 2½c. per pound for lead in pigs and bars, and 2½c. in sheets, pipe, and shot. Crude sulphur has been put on the free list, and a duty of \$4 placed on refined. The Senate fixes the duty on iron ore at 25c. per ton after a lively debate which turned more on what would happen to Charles Schwab than anything else. Party lines are broken down, and Democrats in numbers are voting for higher tariffs, while numerous Republicans seem equally eager to reduce them.

In order to aid the Federal authorities in their efforts to reduce the number of fatalities in coal mines, F. M. Simmons of Raleigh, North Carolina, has introduced into the Senate an amendment to the tariff bill which provides that miners' rescue appliances and miners' safety lamps shall be admitted free of duty until January 1, 1912. The most efficient appliance, the oxygen helmet, is made in Germany. Rescue work in mines is so dangerous that it is not thought wise to take any chances with apparatus not up to the standard. Temporarily, at least, the helmets must be imported.

A bill has been introduced by F. E. Warren, Senator from Wyoming, providing that those who prior to March 3, 1905, in good faith conveyed title to the United States to land in any forest reservation shall be permitted to make selections of an equal quantity of the surveyed, unoccupied, and unappropriated non-mineral public lands, in lieu of the lands thus conveyed. George S. Nixon, of Reno, Nevada, Senator from Nevada, has introduced a joint resolution providing for the erection of a monument in Washington to the late William M. Stewart, for a number of years Senator from Nevada. The statue is to cost not more than \$100,000.

The chief of the Denver Field Division of the General Land Office reports that 90% of the Colorado entrymen in areas supposed to contain coal will elect to take title to the surface, remitting to the United States the coal rights, as recent legislation permits. This indicates the value of this amendment of the coal-land act which was urged by Mr. Ballinger in 1907, when Commissioner of the General Land Office. If the entrymen, on the other hand, choose to contest, then the issue becomes one of relative worth between agricultural and coal values. In North Dakota, to which this act was supposed to be specially applicable, in all but 54 townships the land is found to be at present more valuable for agricultural purposes than for coal.

The regulations for the classification and valuation of the Government coal-lands, as revised in April, provide for fixing higher valuations upon lands underlain by the higher grades of coal. The price of coal-land containing the lowest-grade bituminous coals or lignites is fixed at the minimum provided by law, the intention being to thus encourage immediate utilization of these low-grade fuels. The revised scheme differs from that formerly in force in two general respects. The basis is now specifically that of coal-tonnage, and the land-prices thus determined for the better grades of coal are higher. The plan of valuing the public coal lands by accurate determination of coal quality and tonnage is most equitable, and while adequate returns accrue to the Government, the land-prices thus fixed rarely amount to one-fourth of the royalties prevailing in the same districts.

The present scheme of valuation is as follows: Anthracite and coking bituminous coals are valued at 2 to 3c. per ton. High-grade non-coking bituminous coals are valued at 1 to 2c. per ton. High-grade sub-bituminous and low-grade bitu-

minous coals are valued at ½ to 1c. per ton. Low-grade sub-bituminous coals and lignites are valued at a minimum price fixed by law of \$10 and \$20 per acre. In one township near Rock Springs, Wyoming, the valuation of which has just been completed by the Geological Survey, the coal-land values aggregate \$2,800,000, on the basis of 1c. per ton. The amount for which the Government would have sold these lands on the basis of the minimum price allowed by law, under the interpretation which held prior to 1906, is \$460,000, while under the valuation plan of last year the amount would have been a little less than \$1,000,000.

GOLDFIELD, NEVADA.

Florence Goldfield Mill Extension. — Consolidated Development. — Copper Ore. — Combination Fraction.

T. G. Lockhart, president of the Florence Goldfield Co., has returned from Denver and announces that the capacity of the Florence mill is to be increased at once by the addition of a tube-mill and concentrating tables which will enable it to treat 200 tons daily. At present the plant is treating 120 to 130 tons, chiefly low-grade ore from the dumps of expired leases. Some ore of better quality is being taken from the company's workings, and from those of the Engineers lease and mixed with the low-grade, but the heads are still below \$25 per ton. The raise from the 500-ft. level has advanced 50 ft. In support of their contention that the Florence company should not be compelled to pay bullion tax for the first quarter of the current year, the officials have filed a sworn statement in the office of the assessor, setting forth that they have operated at a net loss during that period of over \$18,000. This came as a surprise, in view of previous announcements to the effect that operations were resulting in a production of from \$50,000 to \$100,000 monthly and affording ground for the inference that a resumption of dividend payments was contemplated. The mine is said to be in splendid condition, but the slime pond, already a heavy expense, is nearly filled after three months use of the mill.

The principal production of ore for the 600-ton mill of the Consolidated Mines Co. is being made from the Combination mine, where at the fourth and fifth levels the Hampton stope is opened to a width of 50 ft. Square sets are being installed. Between the fifth and sixth levels an intermediate cross-cut has entered the pay-shoot, and the uniformity of the ore has now been demonstrated by means of raises and winzes to the sixth level, 380 ft. below the surface. Other parts of the Combination mine are producing good mill ore, including the workings to the west, toward the January claim. Development has now begun from the Clermont shaft, in which stations have been completed at the 800, 900, and 1000-ft. levels. The further opening of the 260-ft. stope in the Lucky Boy claim of the Jumbo, a continuation of the Red Top drift, has developed a body of high-grade ore, but owing to the faulted condition of the vein its extent is still undetermined. In the southeast corner of the Mohawk and extending into the Jumbo claim, an orebody is being developed that is apparently second in volume only to the Hampton stope bonanza, though of lower grade. The stopes in this vein are now opened three abreast, each from 12 to 20 ft. wide, and the ore is opened from the 450 to the 600-ft. level. J. H. Mackenzie, manager, states that additions would probably be made to the new mill during the present year. Since that statement was made the reserves have been increased by a volume never anticipated, and it is probable that the plant will be enlarged, by the addition of stamps, to at least an 800-ton daily capacity.

In sinking the sump below the 400-ft. station of the Victor shaft of the C. O. D. Consolidated the same vein has been cut from which high-grade ore was mined at the 200 and 300-ft. levels. It was from this vein that the first copper ore in the district was taken, the ore running high in gold as well as copper. Below the 400-ft. level the vein carries a fair percentage of copper, but the assays show little gold, and apparently the pay-shoot must be sought by driving on the lead. Production at the 300-ft. level was suspended until the shaft should reach the 400-ft. station, but will now

be resumed from both the 200 and 300-ft. drifts. Nearly 700 ft. southeast of the Consolidated company's Clermont shaft the Grizzly Bear Mining Co. has penetrated the Clermont vein, passing through the lode on its dip for 40 ft. Quartz, but no ore of commercial value, was found in the shaft. Drifts will be driven both ways while the shaft is continued to 800 ft. At the 600-ft. level of the Combination Fraction a cross-cut is being run to the northwest in the effort to cut the Hampton stope vein of the Combination, which is thought to dip into Fraction ground at about that depth. The Fraction is producing 80 tons daily of \$37 ore, the product coming chiefly from stopes between depths of 250 and 400 ft. The Little Florence lease on the Fraction is not producing, but has developed a good tonnage of medium-grade mill ore. On the Combination No. 2 the Stoneham-Moore-Griffiths lease is taking out small quantities of rich ore from a narrow vein in a raise from the 500-ft. level and will continue sinking the shaft an additional 200 or 300 ft. The Daisy mine continues daily shipments of \$100 ore, and is developing at the 500-ft. level. The Great Western mine, at Horn-silver, for some time past a producer of silver-lead ore, has been closed down owing to the high cost of production and transportation, amounting to \$35 per ton on its \$40 product.

DENVER, COLORADO.

San Juan District.—Cripple Creek. — The Golden Smelter and Clear Creek Mining.—Wyoming Coal Land Fraud.

The shipments from the San Juan district show a marked increase for the month of April, the total being 3450 tons of concentrate and 25 tons of crude ore. The Gold King was the heaviest shipper, sending out more ore than any other two mines. This mine is closed down temporarily by the fire which destroyed its surface plant on May 18. The buildings were burned a year ago on almost the same date. Sparks from a passing engine are believed to have been the cause. The Esmeralda Mining Co., owning the Esmeralda mine, in Mining gulch, 7 miles northeast of Silver ton, is making arrangements to install a large cyanide plant. S. S. Watson, representing the New York owners, is directing the work. The Ouray Mine Operators Association has appointed a committee to investigate the Fink furnace.

The Cripple Creek drainage tunnel continues to figure prominently in the affairs of that camp. Thirty thousand of the \$160,000 necessary to complete the tunnel has been pledged, most of it, however, contingent on the subscription by the Colorado Springs Mining Exchange of \$5000. Probably the most serious accident to date in the drainage tunnel occurred in the north heading from the intermediate shaft, on May 17, when a missed hole was drilled into. One miner was killed and six others injured by the resulting explosion. The Gold Dollar Mining Co. is being sued for trespass and for wrongful extraction of ore by the owners of the Gold Bug claim. The claimants ask \$150,000 for bullion extracted, and \$25,000 damages because the Gold Bug claim has been covered in part by the dump of the Last Dollar. The Doctor Jack Pot Mining Co. has declared a dividend of $\frac{1}{2}$ cent per share, payable on June 1. The dividend amounts to \$14,000, and is the first for some time. A. E. Carlton has been elected president of the company. An 18-month lease, with royalties graded from 15% upward, has been secured by Haas & Meyers on the Maria A., on Raven hill. The lessees have begun to retimber the shaft.

Clear Creek miners are rejoicing over the fact that the Carpenter smelter, at Golden, is to be operated again. This plant was designed to handle the low-grade ores from this district, and was very successful until forced to close by lack of ore. This smelter is to be operated by the North American Smelter & Mines Co., of which H. A. Riedel of the Riedel Investment Co. is general manager. This company controls the Donaldson mine, the Centurion Mining Co., and the Banner Consolidated Mining Co. From these a steady supply of ore is believed to be assured. Certificate of incorporation of the Adudell Mines Co. has been filed with the County Clerk. The capitalization is for \$1,000,000. The company is already operating the Adudell mine, in Russell gulch, and is

shipping by tram to the Iron City mill, at Black Hawk. The mill is under lease to the company.

The Owl Creek Coal Co., operating in the vicinity of Gebo, Big Horn county, Wyoming, has got into trouble with the Federal Government. The charges involve the acquisition of coal lands through the use of dummy entrymen. The summoning of 47 persons, living in New York, as witnesses was the first intimation that the Government had been making careful investigation of the alleged land frauds.

NELSON, BRITISH COLUMBIA.

Silver King.—Eureka. — Granite-Poorman. — Queen Victoria. — La Plata.—Hall Smelter.

The mines being operated in the vicinity of Nelson are the Silver King, Eureka, Granite-Poorman, Queen Victoria, and several small properties. The Granite-Poorman is a gold mine; the main product of commercial value of the others above named is copper. The La Plata, formerly known as the Molly Gibson, is a silver-lead-zinc property, situated on Kokanee creek, northeast of Nelson and on the opposite side of the west arm of Kootenay lake. The Silver King mine, shipments from which were lately resumed, was the first lode mine worked in Nelson district. It is situated on Toad mountain, a few miles south of the town. Mineral was accidentally discovered in 1886 on one of the claims now constituting the group. The property was sold in 1893 to an English company incorporated as the Hall Mines, Ltd., and reorganized in 1900 as the Hall Mining & Smelting Co., Ltd. The mine was equipped with machinery and for years was productive, yielding ore carrying considerable silver and copper. Later it was worked under lease by M. S. Davys, and then was idle until the current year, when, after the Hall M. & S. Co. had been compelled by financial difficulties to entirely suspend operations, Mr. Davys organized in London, England, the Kootenay Development Syndicate, Ltd., which acquired the property under lease and option of purchase. A local board of management was appointed, and one of its members, Louis Pratt, now of Nelson and well known for years as manager of a Slocan district silver-lead mine, was placed in charge of operations. The aerial tramway from the mine to the smelter at Nelson was put in working order, electric power was substituted for steam at the mine, the workings were pumped out down to the seventh level, and shipment of ore was resumed. During April nearly 1500 tons were sent to the Consolidated M. & S. Co.'s smelter at Trail. The average grade of ore is understood to be similar to that obtained during earlier operations. In 1904, 4340 tons of ore mined averaged 21.4 oz. silver per ton and 3.66% copper. Under the old regime the mine was opened to 1000 ft. depth. It is not intended to unwater the lowest levels for a time.

For a time development of the Eureka was by means of a shaft and openings, but last year driving a cross-cut was undertaken and about 500 ft. driven. This year the extension of this working to about 750 ft. from the adit portal, and raising therefrom to connect with the shaft, is in progress. No ore has been shipped since 1907; production in that year was 620 tons of ore, averaging gold 0.21 oz. and silver 2.5 oz. per ton, and copper 5.5%. The property is owned by the Eureka Copper Mines, Ltd., of which company L. B. Reynolds of Nelson is managing director. The Granite-Poorman mines, owned by an English company named the Duncan United Mines, Ltd., and for some time successfully operated by it, are under lease and option of purchase to Thos. Gough, J. P. Swedborg, and E. E. Guille, who have mined and milled about 6000 tons of ore during each of two years just past. Last year approximately 1900 oz. gold and 290 oz. silver were recovered from 6160 tons of ore. Underground development is being continued, while a number of ground-sluice ditches have uncovered some promising lodes. Recent surface improvements include renewal of battery blocks under the mortars of a 10-stamp mill and erection of ore-bins and pockets. The Queen Victoria is now under bond to the Consolidated Mining & Smelting Co. of Canada, Ltd., which is further prospecting the big orebody occurring on it. The property is situated about seven miles

from Nelson and a short distance from the Canadian Pacific railway. For a time it was worked under bond by James Cronin of Spokane, Washington, and associates, who shipped to the smelter at Trail about 3500 tons of ore averaging 2.6% copper and only a little silver and gold. When the price of copper fell considerably, this bond was thrown up. During 1908 New York capitalists were interested in it, and J. Parke Channing had a representative on the ground. A 6-drill air-compressor, electrically driven, was installed to expedite prospecting operations. Early this year these operations were discontinued, and though no reason was assigned, it was understood that the ore was not high enough in grade to induce purchase of the property when the price of copper was low. Before ore was shipped the orebody was described by a well known engineer as being "a bluff of copper ore standing out in bold relief from the country rock, measuring along the face, that is, the strike of the deposit, more than 400 ft. in length. Across the deposit horizontally the width is 300 ft., and the ore shows vertically for 150 ft. with a westerly dip." Among others who have examined the property is Walter Harvey Weed, who visited it early in 1908.

Other properties about Nelson which have been productive to a considerable extent in past years are the Fern and Athabasca-Venus, both having stamp-mills; also the May and Jennie, first worked by A. H. Kelly, and afterward by

Hall Smelter at Nelson, B. C.

the Reliance Gold M. & M. Co., which installed a Blake crusher and rolls, 6-ft. Akron Chilean mill, and cyanide plant with a 12-ft. Hendryx agitator. Much experimental work was done, but of late mine and mill have been idle. The La Plata was operated for a time with an average of about 50 men in mine and mill, but lately it has not been worked. The vein is in a granite formation and has been opened by four working levels and a prospecting drift. The ore is quartz, with siderite, argentiferous galena, and blende. No. 5 tunnel is at an altitude of about 6600 ft., which is 2200 ft. above the mill, and there is an Otto aerial tramway 8450 ft. long between the two. The mill equipment is complete. The product was 5 tons of first and 10 tons of second-grade concentrate, and 2 tons of hand-sorted ore, from 80 tons delivered daily by the tram. Mill-feed averaged 4 to 5% lead and 20 to 26 oz. silver per ton; concentrate and picked ore contained approximately 10% zinc. The product was hauled 12 miles by wagon to Kootenay lake, and taken thence by steamer or barge to Nelson, where it was loaded on cars for transfer to the smelter.

The Hall M. & M. Co.'s smelter at Nelson has not been operated since the suspension of the company. It was established to treat Silver King copper-silver ores, but later the furnaces were altered to adapt them to lead smelting.

It looks as though the affairs of the Sullivan Group Mining Co. would now be adjusted without participation of the shareholders. The attempt to resuscitate the old company having failed, it is now planned to reorganize, issuing first preferred stock, bearing 7% annual dividend, to cover the amount of the bonded indebtedness, with interest, over \$400,000. Second preferred stock, bearing same dividend

rate, will be issued to cover the other liabilities of the company, something over \$60,000. This stock will be subject to recall by the company, at par. Common stock will also be issued to the amount of the first preferred stock, and will be divided among the bondholders, who will be assessed for the cost of reorganization. This will adjust things as far as the bondholders and creditors are concerned, but is hard on the stockholders. It is pleaded, however, that only about two-thirds of the stockholders were willing to come into the plan first proposed, which embodied an assessment. The company has a promising mine, in which there is a large quantity of ore ready for stoping.

BUTTE, MONTANA.

Churchill Separator.—Alex Scott Mine.—Zinc Works.

An experimental mill has been constructed on the site of the old Yankee Boy mill by the Churchill Co. of Boston to try a new separator. Creighton Churchill, vice-president and general manager of the company, is the inventor, and is in charge of the work here. The mill is of a 24-ton capacity. The system involves reducing the ore by crushers and rollers to a maximum of $\frac{1}{4}$ in., and by means of trommels, revolving screens, delivering the ore to 3 Churchill separators. No. 1 machine takes ore of sizes between 6 and 3 mm.; No. 2 machine takes that between 3 mm. and $1\frac{1}{2}$ mm.; and No. 3 takes the entire undersize through a $1\frac{1}{2}$ mm. screen. The tailing discharged from machine No. 3 is sent to 2 Wilfley tables without classification. With the mill arranged as described, a test run of 48 tons of ore containing $16\frac{1}{2}\%$ of iron and $1\frac{1}{2}\%$ of copper resulted in obtaining $16\frac{1}{2}$ tons of concentrate running 41% iron and 3% copper; and this was obtained without the use of jigs. About one-half of this concentrate produced came from the tables, and the remainder from the Churchill machines. This run was made to get as high concentration of iron as possible, on the supposition that the copper, being of a high specific gravity, would to a certain extent take care of itself. The approximate result of the run was an extraction of 89% of the iron and 67% of the copper, the low extraction of the copper being largely due to the amount of slime produced by crushing all the ore to a quarter-inch size. Another run on zinc ore, although the ore was not carefully sampled, gave results which led to the introduction of a machine in the Butte Reduction Works, where it will be tested under practical conditions.

The machine is being tested in Butte because Butte ores are probably as hard to treat as any copper ores known. By reducing the ore to $\frac{1}{4}$ -in. as a maximum size to start with, the sliming tendencies are given full play, whereas, if the mineral had been taken out at the maximum size of 2 in., considerable re-crushing would have been avoided and consequent loss due to sliming been eliminated. The 3 machines are installed on the second floor, and occupy floor space of 2 by 7 ft., the head-room being about 3 ft. The entire installation, excluding the space occupied by the two Wilfley tables, is 20 by 24 ft. In appearance the machines resemble cone classifiers, having an over-all diameter at the top of 24 in., and being 33 in. high. The theory of the Churchill separator is that of the separation of the valuable from the non-valuable portion of the ore by means of a rising current of water, combined with centrifugal force. Detailed description of the device is withheld for the present.

The Alex Scott Mining Co., which is successor to and a reorganization of the Butte-Montana Co., has received a new Nordberg hoisting engine, which will be installed shortly. The present work in the Alex Scott is confined mostly to opening orebodies and developing the vein on the 1000 and the 1200-ft. levels. On both the company is driving on the vein east and west. Some good ore is being taken out in the course of development. On the dump there are now more than 500 tons which it is claimed will average 6% in copper.

The new zinc concentrator installed at the Butte Reduction Works is working satisfactorily. There are a number of properties to the north and east of the city which it has been impossible to work at a profit because of the presence

of zinc. Last year a Boston corporation owning and operating zinc plants in Platteville, Wis., Salt Lake City, and at various other places, sent an expert to Butte to investigate the possibilities of operating a zinc plant at Butte. After several months the expert was withdrawn. It is understood that the reason the field was abandoned was that the available amount of zinc ores was not sufficient to justify the investment of the \$75,000 to \$100,000 necessary.

MEXICO.

Mexican Northwestern.—Velardeña.—Torreon.—Orient Railroad.—El Oro Camp.—Chihuahua Smelter.—Candelaria.—Hinds Consolidated.—San Luis, Durango.

The plans of the Mexican Northwestern Railway Co., of Canada, are much more comprehensive than was at first supposed. F. S. Pearson's engineers have been over the line of the proposed railroad from Monclova, Coahuila, to Chihuahua, and it is believed that the concessions for this will be taken over and the road built to connect with its Chihuahua & Pacific and the Sierra Madre & Pacific railroads, which now form a continuous line from Chihuahua to Madera. The Pearsons also have a concession for the continuation from Madera north to Terrazas, the southern terminus of the Rio Grande, Sierra Madre & Pacific, running out of Ciudad Juarez. Attempts have been made to acquire this road also, but as yet they have not been successful. A concession has been obtained, therefore, for paralleling the Rio Grande, Sierra Madre & Pacific, so as to enable the Mexico Northwestern to get into El Paso. From Guzman, on the Rio Grande, Sierra Madre & Pacific, a line is being surveyed to Douglas, Arizona, and on to Cananea, Sonora. These lines of railroad, with the Sierra Madre Land & Lumber Co. holdings (also acquired by the Mexico Northwestern) would give Pearson and his associates practical control of the Mexican coal and lumber business in Sonora and the adjacent section of the west coast.

In the State of Durango, outside of Velardeña, matters appear to be comparatively quiet. At Topia there is some active work, and operations have been resumed on the San Fernando by J. P. Canfield, who is cyaniding the ore and shipping out the bullion. At Inde the Inde Reduction Co. has taken over the Madrigal group, which yields a lead-copper ore, with some silver and gold. At Velardeña there is unusual activity. The mines and smelter of the American Smelters Securities Co. are being operated at full capacity. At the smelter, for some time after blowing in, many metallurgical difficulties were encountered, but these have now been overcome and excellent results are being obtained. This plant was built originally for treating copper ore, but is now principally a lead smelter, the change having been made necessary to correspond to a change in the ore. The mines now give a lead production greatly in excess of copper. The erection of a copper converter stand at the Torreon plant is proceeding. It is not probable that the completion and blowing in of the converter will be rushed, for Torreon's receipts of copper ore can not now be sufficient to keep a converter continually in blast, and it would certainly be cheaper to continue to sell matte to the Aguascalientes plant of the American Smelting & Refining Company.

Arthur E. Stilwell, president, and Edward Dickinson, vice-president and general manager, of the Kansas City, Mexico & Orient Railway Co., were in Boston recently. There is a Boston investment of about \$800,000 in this property. Mr. Stilwell says: "We have gone through a hard two years, but have been able to continue our building operations. Last year we built 135 miles of new road and, other than the St. Paul, I know of no railroad in the United States which did better than this. We have a total of 859 miles of railroad built and in operation, out of a prospective total of 1659 miles when we have built through from Kansas City to the Pacific. We have already raised a total of \$20,000,000, and it will take \$15,000,000 more to complete the road. We hope to have it completed within two years. The road we now have in operation is more than paying operating expenses. In Mexico about 65% of our line is in

operation, and we have already gone over the continental divide with a grade of about 2½%, though it has been stated that we could not get over the divide unless we had engines with teeth or wings. We have been successful in London in raising money. We expect in the not distant future to have a public issue of \$3,000,000 bonds in Paris and \$5,000,000 in London."

In the State of Mexico, camp of El Oro, the Dos Estrellas continues with a production of about 30,000 tons of ore per month and a net profit of ₧400,000; the Victoria y Anexas is driving both east and west cross-cuts at the rate of 5 metres per week, but as yet there is no change, while in the cross-cuts at the Descubridora small stringers are showing. In the Esperanzas the rich quartz sulphide vein has been opened on the ninth level, greatly to the encouragement of the management and the company.

It is stated that the American Smelting & Refining Co. has approved the plans for the additions to the present Chihuahua plant. These will consist of additions to the power-plant and of two new stacks in the furnace building, giving a total of five stacks, with a smelting capacity of 750 tons of lead ores per day. This will allow of an appreciable increase in the company's Santa Eulalia shipments above what is being sent to the El Paso plant. The introduction of electric motors and hoists where steam is now used will effect a much more economical handling of material. The changes may be completed by the end of the current year.

At San Pedro, on the Rio Grande, Sierra Madre & Pacific railroad, the Candelaria Mining Co., whose properties have been practically closed for several years, have been able to unwater the old workings and resume operations. The shipments at present amount to 20 cars per week to the El Paso smelting works, and from 8 to 10 cars per day will be shipped by the end of July. The statement just made by the Rio Plata Mining Co. shows its property to be a notable one. Final payment of ₧50,000 for the mine, on the total of ₧730,000, was made on May 4, and since the Santa Barbara mine, in the Guazapares district, was taken over, two years ago this month, the product of the mine has paid for all running expenses, for the erection of a 25-stamp mill, and for the entire purchase price of the mine, with the exception of the ₧50,000 above mentioned. The ₧50,000, the 275-hp. hydro-electric power plant, and the 100-ton cyanide addition to the mill have been paid for out of the sale of stock. There are 20,000 tons of ₧40 ore on the dump awaiting treatment. The report of the Batopilas Mining Co., in western Chihuahua, gives as the output for the last fiscal year 931 bars of silver bullion, or 839,865 fine ounces of silver, an increase of 8328 oz. over the output in the previous year, but the drop in the price of silver was such that the profits amounted to only \$57,445, a decrease of \$28,221 from those of the previous year. As a consequence, no dividends were declared, the profits going into the surplus fund. For the Palmarejo & Mexican Gold Fields, Ltd., where in twenty years ₧5,000,000 has been spent, E. T. McCarthy has recommended the expenditure of another ₧400,000. It is the purpose of the company to increase its capital stock by £175,000. Thus it will be possible to block out sufficient ore to keep a 250-ton mill supplied for two years. In the Parral district the Hinds Consolidated M. Co. is successfully operating its small mill and is producing a carload of concentrate per week. Plans are now being drawn, based upon the results of the small mill, for the erection of a 500-ton mill, in two units of 250 tons each. At the Tecolotes mill of the American Smelters Securities Co., by direct re-crushing, classification, and fine concentration, 800 tons per day of ore is being treated, and the mill is running over 89% of full time. Some 40,000 tons of zinc middling has accumulated, awaiting the installation of a magnetic separator, for which it is said appropriations have now been made. W. E. Simpson, formerly of Kalgoorlie, Australia, has recommended the Broken Hill methods for handling the complex sulphide ores at the San Francisco del Oro, at Parral.

The San Luis Mining Co., controlled by the Haggin-Hearst interests, is about to install 18 Merrill single-stamp, 1000-lb. batteries, with an appropriate complement of tube-mills, at its mines near Socavón, Distrito de San Dimas, Durango.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A cord (128 cu. ft.) of 4-ft. hardwood usually contains about 83 cu. ft. of solid wood; a cord of 3-ft. wood averages 83½ cu. ft.; of 2-ft. wood, 84 ft., and of 1-ft. wood, 85 ft. The conifers, softwoods, contain 90 to 96 cubic feet.

Scale in boilers may sometimes be prevented by the use of glycerine. This acts by increasing the solubility of the calcium and magnesium salts, and when the limit of solubility is reached, causes them to separate in a gelatinous form which remains in suspension.

Amblygonite, the phosphate of lithium, has been found in commercial quantities only near Pala, San Diego county, California. It contains a higher percentage of the metal than lepidolite and spodumene, the silicates, but being less abundant is not so important as an ore.

Asbestos is finding a new field as a result of improved construction of electric railways. The need of an insulating material less brittle than glass and porcelain and more durable than rubber, has led to the adoption of new compositions which, with asbestos as the base, possess both tensile strength and heat-resisting properties.

Manjak is a local name applied to the glance pitch which occurs commercially upon the island of Barbados. Manjak is a variety of asphaltum which resembles gilsonite in appearance but is more brittle and friable. It is a pure hydro-carbon, and is used in the manufacture of high-grade water-proofing, varnishes, and insulating compounds.

Zinc is often used to prevent corrosion of boilers. Its efficiency is due to the fact that any metal with a greater tendency than iron to dissolve, on which hydrogen is liberated with more difficulty than on iron, will protect the latter at the expense of the more soluble metal. The protection, however, becomes ineffective in pure water at a distance greater than about an inch. Salt or some other electrolyte will extend the zone to 20 inches or more.

A mining claim which by location monuments proves to be longer than 1500 ft. may be reduced in an amended location notice, cutting off the excess at either end. In a case referred to us, the assessment work was done so close to one end of the claim as originally located, that curtailment applied to that end would leave the development workings outside the rectified boundaries. Manifestly the lopping off would be done at the opposite end in such a case.

Flint pebbles come mainly from the coast of Greenland and on the beaches between Havre and St. Valéry-sur-Somme in France. It is estimated that the French deposits cover a distance of over a hundred miles, and yield annually for export, principally to the United States, Australia, and the Transvaal, from

13,500 to 14,000 metric tons. These pebbles are a calcedonic variety of silica occurring in the Cretaceous chalk. They are irregular in shape and size, and extremely hard. The introduction of the tube-mill has led to a rapid demand for them. In America, black flint pebbles occur along the Colorado river in Texas, in Florida, California, Kansas, and in other States.

Cementation index is a term applied to the hydraulic activity of various cementing materials. Its value for any limestone or cement may be found by applying the formula:

$$\text{Index} = \frac{\text{CaO}\% + 1.4\text{MgO}\%}{2.8\% \text{ SiO}_2 + 1.1\% \text{ Al}_2\text{O}_3 + 0.7\% \text{ Fe}_2\text{O}_3}$$

The index of natural cements varies from 1 to 2, but usually falls between 1 and 1.15. For portland cements 1 is the ideal index.

Phosphate rock is a general term for several forms of amorphous material containing more or less phosphate of lime. Variable quantities of carbonate of lime, of silica, and other substances are present. Numerous grades of rock, such as hard rock, soft rock, land pebble, brown rock, white rock, etc., are recognized in the trade. These terms have important but local meanings, and are not uniformly applied, even in individual producing regions.

Mica is widely distributed, but usually in flakes and crystals too small to be of value. Both biotite and muscovite occur in igneous and metamorphic rocks, as well as in sediments derived from them. Phlogopite appears to be confined to metamorphic rocks, and generally with relations indicating its igneous origin. Muscovite is the mica mined in the United States and India, while phlogopite is obtained in Canada. The mica mined near Custer, S. D., is found in pegmatite.

The nominal horse-power required to thaw 3000 cu. yd. of gravel per day can be estimated. The figures are based on the assumption that one ton of coal will raise the temperature of 200 yards of gravel 50°, that 0.3 lb. of coal is burned per square foot of heating surface, and that 12 sq. ft. of heating surface equals 7 hp.; then:

Nominal boiler horse-power	350
Tons coal per day	15
Cords wood per day	30

Sulphur and sulphuric acid in the United States are derived from native sulphur, from iron pyrite mined specially for use as a source of sulphuric acid, and from sulphides carrying workable percentages of copper, lead, zinc, or other metals of value. In the last-mentioned case the acid is a by-product. Abundant fumes for making acid are available from the last source, but owing in part to the common presence of harmful impurities, and in part to the usually necessary position of smelters away from centres of manufacture, relatively little is utilized. Since commercial acid contains large quantities of hydrogen and oxygen, obtained from the air and from water, it is cheaper to ship sulphur to the place where the acid is to be used than to ship the acid itself.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Weight of Stamps.

The Editor:

Sir—The most economical weight of stamps has been much discussed, and the practice in various parts of the world, under conditions of reasonable cost of iron, steel, easy transportation, and an abundant mining capital under superintendence of competent engineers, shows a variation ranging ordinarily from 750 to 1600 lb. in common use. Stamps weighing 1750 lb. have been used experimentally with favorable results on the ores of the Transvaal. In these goldfields heavy stamps are general. Increased weight of stamps has unquestionably been brought about by reason of the character of material delivered to the mills. The ores supplying these mills during the earlier period of activity had been softened by oxidation and were easily crushed. Stamps of a light weight, varying from 900 to 1000 lb., with screens of 22 to 24 wires per inch, gave a duty of 5 tons per stamp per day.

In the deep levels, now well below the oxidized zone, the matrix of the reefs as well as the enclosing quartzites, produce an exceedingly tough and hard material. The quartzite country rock becomes mixed with the reef material in working out the arbitrary stoping widths there customary. This quartzite is intensely firm and without lines of cleavage. The pebbles embedded in the reefs are themselves more resistant to the stamps than the quartz which surrounds them. The weight of the stamp is therefore adapted to the material to be crushed.

The high stamp-duty lately obtained in these fields with newly erected machinery equals at some mills 9 tons per day. It has been largely made possible by improved stone-crushing plants. In these the rock is first passed through breakers of the Blake pattern, and then through gyratory crushers, such as the Gates, and brought to a size not greater than 1 in. maximum diameter. At the same time the introduction of tube-mills has permitted the use of coarser screens at the batteries.

The weight of a stamp must conform within certain limits to the hardness and toughness of the material to be crushed, so that the resistance of the rock beneath the stamp shall be great enough to prevent the shoe and die from unnecessary fracture, and at the same time obtain satisfactory discharge of the crushed material through the screen. It remains to be proved that the standard of heavy stamps now used on the Rand could be successfully applied to the friable quartz material such as usually occurs in the porphyritic formations in the United States.

In the great improvement in ore treatment at present going on in the Witwatersrand district, it is now, and must remain for all time, a question of management, at what point the pulverization of ore shall cease in the battery and be taken up and continued

in the tube-mill. The greatest of all controlling factors at each separate plant is the percentage of low-grade battery-crushed material allowed to pass through the spitzlutzen or other separating device direct to the percolating tanks that is too low in value for tube-mill grinding. This must be considered when cost of the pulverization is taken into account and in looking forward to an all-slime treatment in any part of the world.

Re-Setting Tappets.

The Editor:

Sir—An article published in the MINING AND SCIENTIFIC PRESS on January 30, by Thomas N. Miller, suggests that consideration of methods of re-setting tappets may be of interest. Mr. Miller states that a first-class millman will set a tappet on one stem while the remaining four are running, thus continuing the crushing without loss of time. In discussing this point, Robert H. Richards, in his work on 'Ore Dressing' agrees with Mr. Miller, with one exception. He cites the practice at the Utica mill, Calaveras county, California, "where the periodic shifting of tappets to allow for wear of shoes and dies is usually done without hanging up more than one stamp at a time, except that when a feed-stem is adjusted, all the others must of course be hung up. When the battery-man is ready to set tappets, he allows the battery to 'pound out' so that the stamps hit the dies. He then measures the drop with a stick, and notes it mentally. Next he hangs up the stamp and loosens the keys so that the tappet can be moved the desired amount by striking it from below. The keys are then tightened, and he goes on to the next stamp."

Additional suggestions that I make tentatively are the following: should one or two tappets only in a battery require immediate re-setting, the alteration needed to approximate the correct drop may be estimated offhand, and the tappet re-set. Later, as occasion offers, or when necessary, the drop of each stamp should be measured in the mortar and the corrected position of the tappet marked on the stem above the tappet, which may now be re-set at will.

As given in the quotation from Richards' 'Ore Dressing', common practice in the main consists of hanging up the stamp, loosening the tappet-keys, and raising the tappet by striking the upper flange from below. Raising the tappet, however, by striking it from below with a hammer often proves a tedious and laborious undertaking, and prompts the following more effective procedure. Hang up the stamp; loosen the keys sufficiently to allow the cam to drive the tappet; drop the stamp, and catch it again on the finger just before the tappet passes the mark on the stem, when it may be nicely placed on the line with the hammer, and the keys again seated.

To increase the drop, the driving-power of the cam will be found equally serviceable, especially in the case of a tight tappet. After having loosened the keys, drive the tappet upward by means of the cam, at least to start it, and if necessary clean the stem; then raise the stamp and lower tappet to line.

Battery-men alone will appreciate the time and

labor saved by using the cam instead of a hammer for starting and placing tight tappets. Moreover, when decreasing the drop, its use disposes of Mr. Richards' one exception, as the feed-stem is readily set without hanging up the other four; and it becomes unnecessary to allow the battery to 'pound out'. In reality, a stamp may be dropping three-fourths of the time required for setting its tappet, and at the same time be crushing ore. To work to the best advantage in setting tappets next to the posts, a battery-man should be able to strike both right and left-handed with equal facility.

Unwatering an Old Mine.

The Editor:

Sir—In your issue of May 8 the question is raised by 'Problem' as to the proper machinery to install in unwatering a mine 1500 ft. deep, which is briefly described. I have recently had charge of an undertaking of a similar nature, and a record of my experience may be of value. At the mine in question several shafts had been previously sunk, all of which had caved, either at the surface or in depth. It was decided to repair and pump out the deepest shaft, which had caved at the surface, but was presumed to be intact below. This shaft had three compartments, and was about 900 ft. deep, being on an incline of 70 degrees. Although the vein was at a depth of about 30 ft., in sinking through the caved dirt from the original position of the collar, as indicated by the stringers on the old head-frame, no solid rock was found till a depth of 70 ft. had been reached. Here the original foot-wall side of the shaft was found, but the solid hanging wall was not reached until the shaft had been sunk 150 ft. Below this the shaft had not caved, but was filled completely with dirt caved from above. No timber was found in the dirt until the shaft was within 30 ft. of the ground-water level, which was at a depth of 260 ft., and no timber was found in place above 290 ft. Immediately above water-level the shaft was filled with broken and twisted rails and pipes, partly mixed with and resting upon a mass of timber, the old shaft-sets, which had apparently fallen before the rock gave way. Below 290 ft., that is, 30 ft. below water-level, the timber was nearly all in place, and there was no dirt in the shaft.

As the mine was situated on the railroad, with a spur to the shaft, steam was used for power, and the equipment for the first part of the work consisted of boilers and a small, double-cylinder geared hoist and a bucket. A larger hoist was also installed, and a 10-drill air-compressor, but these were not used until after water-level was passed. When the water was reached in the shaft, a No. 8 Cameron pump was used to handle it. This pump was run by air, and threw to a station-pump, run by steam, on the 250-ft. level. Below 290 ft. the water was pumped out of the shaft by two No. 8 Cameron pumps or one No. 10, run by air, and throwing to station-pumps set at intervals of 200 to 250 ft. A No. 9 Cameron sinker was used part of the time, running with steam, but it made the shaft

too hot, and when running with air it used more air than a No. 10.

In this case it would have been difficult, if not impossible, to have bailed out the shaft below the point where the timber was found in place, because of numerous platforms and timbers across the skip-roads, left there by the former owners when they were taking out pipes and rails while the mine was filling up. An air-lift was tried for a time, but it was found to be impossible to give it sufficient submergence, on account of the obstructions mentioned.

In the case mentioned by 'Problem' it will be necessary to have a hoist in any case, in order to repair the shaft, and if it is found to be possible to use a bailer, that will probably be the most convenient and inexpensive method of unwatering. In considering this, it must be remembered that bailing water from a flooded shaft is hard on a hoist, and that the wear and tear on the machinery would be severe, especially if only one bailer were used, and it might be necessary to replace the hoist before mining operations could be conducted on any but a small scale.

LUCIEN EATON.

Iron Belt, Wisconsin, May 15.

The Editor:

Sir—Referring to the letter written by 'Problem' regarding the best method to be used in unwatering a mine on the Mother Lode in California, assuming that the total water to be pumped from the mine is now 40,000,000 gal., and that 90 days can be devoted to this work, my recommendation is as follows:

Install a 3-stage vertical turbine sinking-pump, direct-connected to a 30-hp. motor, and pump the water down to the 340-ft. level, to an old pumping station. At the 340-ft. level we would install a 3-stage horizontal turbine station-pump, direct-connected to a 30-hp. motor. The sinking pump would then be used to go down to the 700-ft. station, delivering the water to the station-pump at the 340-ft. level. Upon reaching the 700-ft. level a duplicate station-pump would be installed and sinking pump used to go down to the 1000-ft. level, delivering water to the station-pump at the 700-ft. level. A duplicate station-pump could then be installed at the 1000-ft. level. The electric sinking pump could then be used on the 1500-ft. level, taking the water out to a depth of 350 ft., or 1350 ft. below the surface, at which point a new station would be made and a duplicate station-pump installed. The sinking pump would then continue to the bottom of the 1500-ft. shaft.

With this arrangement there should be provided, and held on hand for emergency use at the mine, one extra duplicate station-pump with motor, for immediate service in case of a break-down on any of the station-pumps. There should always be provided and kept on hand at the mine duplicate parts of the station-pumps that are liable to breakage, such as shafts, impellers, etc. Under this arrangement each of the pumps mentioned would have a capacity of 200 gal. of water per minute, so that the mine could be unwatered in the time specified. The approximate cost of the sinking pump, 5 station-pumps, electric hoist for handling the sinking pump, transform-

ers to transform from 11,000 volts down to 440, would be \$10,000, delivered at the mine.

The size of the shaft will not permit of the use of any type of pump other than a turbine or a Cornish pump, which would have a capacity of 200 gal. per min. The efficiency of the turbine pumps would be 60 to 65%, under the conditions specified, whereas on the Cornish pump we do not believe that, when the rods and bobs are taken into consideration, the combined pump efficiency would be over 40%. If a well constructed turbine pump be used, with ample bearings and placed on a good foundation, the danger of break-down is no more than is experienced with a Cornish pump, and the damage resulting from a break-down would almost entirely be eliminated by having on hand a complete duplicate station-pump, which could be set in place quickly and put in commission. For the conditions as outlined I claim for the turbine over the Cornish pump, that the first cost would be cheaper, the cost of installation less, the efficiency higher, and the flexibility regarding capacity greater.

E. P. McMURTRY.

San Francisco, May 7.

Simple Control in Cupelling.

The Editor:

Sir—The following method of cupelling is by no means new, but a description may be of value to any assayer who has never heard of it. It is used at Mina Santa Francisca, Asientos, Mexico.

In the front of the muffle a row of old cupels is placed bottom side up to keep the cold air from striking the first row of cupels. The muffle is filled with new cupels, excepting an inch or two at the back. The reason for omitting the last row is not that they would work too hot, but that as a rule any assays freezing are in the farthest row in the muffle. While the cupels are warming the fire is fed with fresh coal. When the cupels are thoroughly heated the lead buttons are dropped in. Often it is not necessary to close the muffle door, and before the last cupel is dropped into the cupel over half of the assays are opened and driving. This indicates at what heat we try to work. Nothing is done to the fire during the cupellation unless the heat has fallen a little. Naturally this temperature would volatilize some of the silver if no precautions were taken, but it is nicely regulated by means of a cooler. This cooler is nothing more than a piece of plate iron, 9 by 5 by $\frac{3}{8}$ in., riveted to a 5-ft. handle of $\frac{1}{2}$ -in. round iron. It is held for a few seconds just above the hot cupels. For a fulcrum, one of the binders of the furnace which happens to pass level with the bottom of the muffle is used. When the assays have the correct temperature, or when the plate has become hot, it is withdrawn and plunged into a can of water. As a rule, the assays near the sides of the muffle will be hotter than those at the centre; then only the corresponding parts of the cooler are plunged into the water, so when the cooler is again slid into the muffle it will have the cold part nearest the hot cupels.

I can recommend this simple method to any assayer

having a large number of silver assays at one time to carry through. It permits filling the muffle and getting good results on all. With a little practice feathers can be produced on every cupel in the muffle.

G. N. PFEIFFER.

Asientos, Mexico, July 25.

Furnaces for Melting Calcines.

The Editor:

Sir—The building of reverberatory furnaces for use in smelting calcines to produce matte involves certain difficulties which may be best met if the following requirements are kept in mind:

1. The furnace hearth should be long, so as to give room for a region of melting at the highest temperature, and another space or region for the settling or separation of the matte from the slag. The first region should be 50 ft., the second 100 ft. long. Edison in his clinker-burning, revolving-cylinder furnace, used in the making of portland cement, found 150 ft. not too much.

2. The charge should be dropped within the first or melting region where the heat is the highest. Here it spreads out, absorbs heat, both from the liquid bath of matte and slag below, as well as from the heated gases above it. Until we get above the melting point of the charge the heat is useless. According to good observers, and to experiments on the rates of cooling, the speed of heating varies by at least the square of the difference of temperature between the hot gases and the melting point. Thus at 1400° C. the speed of melting would be twice that at 1300°, the melting point of the charge being 1200 degrees.

3. If the air for combustion is pre-heated, the heat obtained is considerably more intense than that from direct firing. Thus by heating the air to 800° C. it is possible to add 10% to the temperature of the gases, or, in place of 1400° in the above example, we would have 1540°, and the speed of melting would be increased by 2.2 times over what it would be at 1400 degrees.

Powdered bituminous coal, as shown by experiments at the Highland Boy smelter, offers considerable advantage over direct firing. In that experiment, using a 40-ft. furnace, the gases were sent into the outlet flues at a temperature so high as to fuse the brick-work.

L. S. AUSTIN.

Houghton, Michigan, May 15.

Mine-air samples, 25 in number, taken to ascertain the effects of smoke-powder, were reported as follows by the Government chemists on the Rand:

No. samples.	Combustion product.	Per cent in air.	No. samples.	Combustion product.	Per cent in air.
25.....	CO ₂	0.301	13.....	CO	0.008
11.....	CO ₂	0.517	3.....	CO and CO ₂	0.000

The normal amount of CO₂ in the atmosphere is about 0.03 per cent.

Magnalium, a new alloy of magnesium and aluminum, is said to be lighter than aluminum and as strong and malleable as brass; it can also be easily turned, planed, and drilled.

MULE-BACK TRANSPORTATION OF SECTIONALIZED MACHINERY.

Written for the MINING AND SCIENTIFIC PRESS
By F. C. ROBERTS and WALTER W. BRADLEY.

The subject of mule-back transportation is an old one. Because of its many supposed limitations and 'impossibilities' this form of transport has usually been considered applicable only to small plants. A notable example of the sectionalization of large-capacity power, mining, and reduction-units, and the transportation of this plant to districts accessible only by mule-back, has been recently afforded in the case of the Ventanas Mining & Exploration Co. in Durango, Mexico, with which the writers were connected as consulting engineer and assistant manager, respectively. The success attained makes pertinent the query, how many manufacturers of mining machinery appreciate the potentialities of business expansion by designing large units sectionalized for mule-back transport? One deterrent has been the 'time honored' load-limit of 350 lb. The fact is that with proper organization of crews, good food, and by

days to make the journey; but with a saddle animal, a man may make it in three or four days.

The veins in the district had been worked in a small way many years ago, first by Spaniards, afterward by Mexicans, and later by four Americans who wandered there nearly 40 years ago. Since they were dependent upon high-grade ore their operations were necessarily restricted; and during the last 10 years or so, they installed almost every type of small-unit plant that had been placed on the market, and they attempted nearly all the metallurgical processes described in the text-books, in an endeavor to treat the lower-grade material. While their efforts were not altogether successful, they deserve a great deal of credit for persistence and pluck in facing unfamiliar conditions of living.

The Ventanas M. & E. Co. had practically agreed to undertake the purchase of the group of veins in the district, and to erect a reduction-plant and hydro-electric power-plant before it was by any means certain that manufacturers would undertake to sectionalize many of the important machines. The capacity of plant fixed upon was about 200 tons (dry

weight) per day, the experimental and metallurgical tests indicating that both in initial cost and in economic treatment of the ore, an 'all-slime' plant was most effective. The fineness of the product was to be maintained so that 90% would pass a 200-mesh screen. The plant was designed and erected by F. C. Roberts, consulting engineer. The selection of the machinery was made with a view to careful sizing and to 'step-crushing', and the capacity of the units was so fixed that

Profile of Route.

the exercise of judgment in assigning loads best suited to certain animals it is possible to handle over heavy mountain trails, loads of 475 to 500 lb., and when necessary as much as 680 lb. in one piece. In the accompanying illustration is shown a mule carrying a section of $3\frac{15}{16}$ in. steel shafting, weighing 580 lb. The town of Ventanas or Villa Corona, as it is officially known, is situated about midway between the city of Durango and the Pacific port of Mazatlán. It is about 20 miles south of San Días, Durango, but it takes two days to make this short journey. It is at an altitude of 1700 ft. above sea-level. Access to the camp is circuitous and difficult. Leaving Ventanas, there is but one route of descent, that along the river-bottom in a westerly direction. The town is accessible by mule-back transportation from Durango practically throughout the whole year, and from Mazatlán for about seven months, either journey requiring about 10 days for pack ('carga') miles. The profile given above will help to convey an idea of the altitudes and conditions met on the trail from Durango to Ventanas. 'As the crow flies', it is approximately 65 miles; but by the route followed it is 105. As already stated a 'carga' mule usually requires 10

the aerial trams, rock-breakers, and sorting-belt were required to be in operation only 10 hours per day. The plant was projected with the idea that the ore should be made to suit the individual units, that is to say, it was contended that the most economic results would follow if the product assigned to each unit was maintained at such a degree of fineness as would best harmonize with the design of that unit, providing, of course, that the selection of units was a wise one. All was planned with the intent that tube-mills should be used as the final crushing-device.

The ore is delivered to a central crusher-station by two automatic aerial trams, furnished by the A. Leschen & Sons Rope Co., of St. Louis, Missouri, and discharged to grizzlies set with 2-in. spacing, the undersize falling directly into bins below, and the coarse to sorting floors convenient to the jaw-crushers. The coarse-crushing equipment, Blake crushers, belt-conveyor, trommels, and rolls, came from the shops of the Allis-Chalmers Co. The sectionalization of these was made up of standard sizes furnished by that firm.

The use of rolls was an experiment in this case,

prompted by the knowledge that skilled labor for stamp-mill practice was considered to be hard to get, and the fact that the pioneers of the camp had used rolls for some years which ran largely without attention, and much better with poor administration than any stamp-mill either of the writers had ever seen. Besides this, Mr. Roberts' preliminary experiments indicated that for producing a $\frac{1}{8}$ -in. product, the rolls gave a lower percentage of slime, and the capacity per horse-power was greater than perhaps could have been obtained with stamps. From the de-watering cones below the finishing rolls, the product is equally divided among 3 Abbe Engineering Co.'s tire-type tube-mills, a fourth mill being used for the oversize. This oversize is elevated from the 4 separating cones below the tubes, by a 22-ft. tailing-wheel, the overflow going direct to the treatment tanks. The agitation plant consists of fourteen 30 ft. diam. by 10 ft. deep steel tanks, equipped for mechanical agitation. After a charge is treated it is transferred to a collecting vat, and thence to a vacuum-filter, then passing through a sand-filter to extractor boxes, filter-presses, and to sumps from which it is pumped back for service. Ground was broken on January 23, 1907, and the tube-mills were first turned over for service on July 19, 1908, the entire plant beginning operation on August 10, 1908.

All machines in the plant are operated by separate 8-40-900-60-2080 General Electric induction motors. There are 14 of these 40-hp. motors, and three 30-hp. Power is furnished from hydro-electric plant situated 5 miles up the river from Ventanas, consisting of 2 impulse water-wheels, furnished by the Pelton Water Wheel Co., of San Francisco, controlling three 12-200-600-60-6600 General Electric alternators. The hydro-electric installation was particularly interesting work; not only because of the theoretical accuracy of the machine supplied by the manufacturers, shown later in the practical efficiency of both water-wheels and generators, but also in the engineering difficulties attendant on the selection of the ditch-route.

As regards sectionalizing, the aerial tramways, although not involving intricate engineering problems, required the exercise of a great deal of care in order to keep within proper limits of weight and to retain the strength where it was required. The method of transporting the cables is shown in the illustration. The coils were made up and tied with wire in the factory before shipping, each mule's load being divided into 2 parts, with about 12 ft. of cable between each pair of coils. The 1-in. track-cable weighed 1.64 lb. per running foot; the $\frac{7}{8}$ -in. track-cable 1.20 lb.; and the $\frac{5}{8}$ -in. traction, 0.68 lb. The coils were so arranged that each mule-load was about 236 lb., or 144 ft. of 1 in., 230 lb. or 192 ft. of $\frac{7}{8}$ in., 240 lb. or 354 ft. of $\frac{5}{8}$ -in. cable. Twelve mules carried the 2300-ft. length of $\frac{7}{8}$ -in. cable. The largest piece of 1-in. cable required 26 mules for its transport. One man was assigned to each 2 mules. The mule at the head of the line was controlled by a lead rope, and each mule's lead rope was fastened to the pack of the mule in front of it. In this way, they were kept at a uniform pace, and with the men distributed as indicated,

the entire train could be stopped simultaneously when necessary to tighten up the cinches, or for other purposes.

The four tube-mills, 20 ft. long by 4 ft. 6 in. diam., were, we believe, the first units of these dimensions and capacity to be sectionalized for mule-back transportation. Each mill is supported on 4 well-spaced, chrome-steel roller-bearings, the heavy bed-plates to which the bearings are fixed being cut longitudinally and transversely into 4 sections, 2 male and 2 female, the inside and bottom surfaces being finished true, and firmly held in position with $1\frac{1}{8}$ -in. bolts. The locomotive tires were cut vertically into 2 pieces, each piece being a ring 5 ft. 3 in. inside diameter, $2\frac{1}{2}$ in. thick, and 3 wide, weighing 350 lb., finished on the inside, bored tapering to fit the packing-rings, and held in place with lug-bolts. All packing-rings, flanges, and gear-wheel castings were cut in 2 parts. The steel shell of $\frac{1}{2}$ -in. plate was cut into 3 butt-jointed sections, each of which was made in 3 segments formed to proper radius, with heavy longitudinal butt-straps. The cast-iron flanges holding the shell-sections in place were riveted to the shell and bolted together. The tube-mill parts were necessarily quite heavy, and some of them offered a little trouble. Perhaps the most difficult loads to handle were the bearing rollers, not so much because of the weight (385 lb.), but because they rested high on the 'lomillos'—a small wooden crib made of four 4 by 4-in. blocks, which rests on top of the saddle. The locomotive tires were also difficult to handle, and the cast-iron heads, because of their large diameter and frailness, required a man to each mule.

The tanks of the cyanide plant, eighteen 30 ft. diam. and 10 ft. deep, and five 24 ft. diam. and 8 ft. deep, offered no mechanical difficulties, but made a large number of plates and an excessive amount of riveting. It was necessary to retain an area not to exceed 17.5 sq. ft. per plate. The maximum size of plates was 5 ft. by 3 ft. 6 in. Each 30 by 10-ft. tank contained 110 plates, about 50 of $\frac{1}{4}$ -in. at the bottom and 60 of $\frac{3}{16}$ -in. on the sides. Besides these were the top and bottom angle-irons, which were cut into 10 segments each. There were in all about 2500 plates to handle, and about 175,000 rivets were driven. The line and counter-shafts of the tanks, made about 500 ft. in all, reducing from $4\frac{1}{2}$ in. diam. down to 3 in., and the greatest length handled was 15 ft. 10 in. The vertical agitator-shafts, 13 ft. 6 in. long by $3\frac{15}{16}$ in. diam., were each taken in one piece, weighing 580 lb. These were carried on picked mules, and 2 men assigned to each mule, one man ahead with the lead-rope, the other behind to steady the load and prevent it from swinging and see-sawing. Heavy pieces like these were handled in relays, changing mules about every 2 hours. One of these shafts is shown in the illustration opposite.

Friction-clutches (Imperial type) were heavily designed not only to overcome the usual starting load of about 15 hp., but to care for such emergencies as when a careless shiftman allows the density of the charge to reach a point equal to 2 charges. The heaviest pieces of these clutches weighed 480 lb. each. The cast-iron crown-wheels, and crosses for

agitator-arms were made in 4 parts, held in place with shrink-rings, bolts, and keys. Outside of the crushing-units and power-plant, there were no pieces which gave great trouble. Pumps up to 300 gal. per minute under 180-lb. pressure, as well as centrifugal pumps up to 6 in., and horizontal, straight-line compressors of a capacity up to 400 cu. ft. of free air per minute, can be dismantled without much trouble, excepting the bed-plates, which generally require to be specially cast in two or more pieces. One of the accompanying illustrations shows the section of a shaft for the mine-hoist, weighing 420 pounds.

The design of the hydraulic plant kept the individual pieces well within the packing limit, but with the extremely careful workmanship and finish, and the fact that many of the cores were bored for a driving fit-bolt, it was as rigid when assembled as could be asked for. This plant included 2 double, 26 in. diam., impulse-wheel units, bed-plates, bearings, shafts, housing, etc., together with 980 ft. of pressure-pipe and 1500 ft. of grade-piping. Some sections of the $\frac{1}{4}$ -in. gauge, 26 in. diam. pressure-pipe, which was furnished in 5 ft. 6 in. lengths, by reason of its weight (396 lb.), and the 30 in. No. 10 gauge grade-pipe, by reason of its bulk, gave some little trouble.

All of the electrical units were assembled and wound at the mine. The 200-kw. generators were housed in skeleton-type frames, cut into 2 pieces, with short legs bolted to a divided bed-plate. The heaviest part of the generators were the shafts, weighing 520 lb. each; while in the induction motors, the rotors weighed 480 lb. each, with shaft pressed in.

The fact that the largest stick of timber possible

and a total of 600,000 ft. B. M. of lumber sawed and packed out on burros and mules. The burros handled the lighter stuff, such as 1 by 12 in., 2 by 4 in., and 4 by 4 in. Some 200,000 ft. B. M. of this lumber was used in flume-construction for the hydro-electric plant.

In the timber transport, each mule carried from 88 ft. B. M. (2 pieces of 6 by 8 in. by 11 ft.) up to 117 ft. B. M. (2 pieces of 8 by 8 in. by 11 ft.), with the average running about 110 ft. B. M., due to the

Agitator Shaft of 3 15-16 Diam., Length 13 Ft. 6 In., Weight 580 Lb.

larger number of 8 by 8 in. handled. The 600,000 ft. B. M., therefore, made about 5500 mule-loads, or 16,500 mule-load days, as the round trip required three days between the saw-mill and Ventanas, and also between the saw-mill and the supply-point for the ditch line, whence it was handled by men. As for weight, 2 pieces of 8 by 8 in. by 11 ft. would weigh from 350 to 400 lb., depending on whether it

Tramway Cable 2300 Ft. Long Loaded on Twelve Mules.

to transport was 10 by 10 in. by 11 ft. long, and that most of the heavy work was made up of 8 by 8 in. by 11 ft. material, necessarily restricted the design of woodwork to certain limits and called for odd spans in order to avoid waste. It also resulted in an enormous amount of splicing, building up, trussing, and bracing; besides consuming large quantities of iron in bolts, rods, plates, and brackets. The main timber district is some five hours from the town of Ventanas, at an elevation of about 8000 ft. above sea-level. A saw-mill of 5000 ft. B. M. daily capacity was put up;

was well seasoned or not, while a few very pitchy sticks, which were actually weighed, tipped the scales at 620 lb. for the pair.

In anticipation of the enormous transport job ahead, the first work undertaken was the building and repairing of about 150 miles of trails. Labor was scarce and was drawn from both the high and low country, but it was not long before it became evident that higher efficiency was obtained, and the cost of accommodations lessened, by separating the coast-men from the mountaineers. At best, the hot-

country natives are not overburdened with clothing, and they simply cannot thaw out in the cold climate of the mountains.

Next came the purchase of pack-mules, organization of permanent trail-gangs for repair work, distribution at convenient points of blacksmith outfits and tools, mule shoes, etc. Not of the least importance was the purchase at market rates and distribution of immense quantities of corn and 'paja' for mule-feed. The purchase and organization of a large pack-train on company account does not at first suggest economy, but having an intimate knowledge of the Mexican packer or *arriero* and having observed the treachery of the packers as revealed in heavy castings lying on out-of-the-way mountain trails, and having 1500 tons of heavy, awkward, mining machinery at the railroad terminus, a staff of expensive skilled foreigners, and a force of skilled Mexicans at the mine, this course was justified in order to ensure a constant supply of material for the construction gangs, and at the same time to exercise control over the transport-rates.

A few Mexican transport-men will take an occasional load of 425 lb. at absurdly high prices, generally at a figure representing three times the value of the mule; but we had many pieces which were absolutely refused at any price. We have known instances in Mexico in which a company has had a heavy piece of machinery left somewhere along the trail after as much as \$125 had been paid for its transportation to the mine. It is customary to advance to packers from 30 to 50% of the total price when starting, and it is not uncommon for them to take half a dozen loads a couple of days out and leave the *carga* scattered along the trail, and migrate, if more than one forwarding agent is handling material.

Our next task was perhaps the most difficult of all, to convince our own packers, as well as outsiders, that the intention was to transport this 1500 tons of heavy awkward machinery to Ventanas. The more enlightened public, after visits of inspection to the railroad station, held animated discussions to determine who was most destitute of reason—the engineer who undertook the design and erection of the plant, or the company that elected to pay for it. The usual day's journey for a pack-mule is from 5 to 6 hours, and during the rainy season (June to November in Durango) the animals are generally turned out and allowed to graze on the new sweet grass, which they prefer to the more substantial corn. Consequently they soon lose their strength to such an extent that they cannot stand up under an ordinary load. In this respect, as well as in the matter of the length of 'jornada' (daily journey), and the weight of loads, a material departure was made from the usual custom, tying up the mules and feeding them. By reason of slippery trails, heavy loads, and 'green' mules, we lost, in all, 38 animals during about 16 months of steady work.

The Mexican *aparejo* (pack saddle) is a large leather bag, divided so as to hang equally over both sides of the mule, and is padded with straw and held in place by heavy breeching and cinches. It covers well the mule's back, and is really better adapted for

packs of all weights and dimensions than the pack-saddles of the western United States. When well secured with the 'diamond hitch' thrown by an experienced *arriero*, there is little danger of the load shifting. A good pack-mule, *aparejado* (wearing the pack-saddle) is worth from \$47 to \$65 U. S. currency, and a poor mule is dear at any price. Effective work depends to a great extent upon the selection and assignment of loads, the *arriero* being guided by the gait and build and degree of 'mulishness' observed. Some mules will worry themselves into a state of exhaustion with a load that they have made up their minds does not suit them. The amount of intelligence displayed by pack-mules is sometimes marvelous. The affection that is shown for the *yegua* (bell-mare), without which a train cannot be managed, reflects another side of the mule's character, which Mark Twain so aptly described when he said "a mule would make love to its keeper for 10 years or more in order to get a chance to kick his head off."

The company's pack-train equipment, comprising about 150 mules, though traveling together, was divided into 3 trains, each having its separate camp and cooking outfit, saddle-man, cook, and force of *arrieros*, with a head-packer in charge of the entire equipment. While, as stated before, the company established supply and storage-stations for corn at convenient points along the route, it was not possible to have these at every stop the trains would make. For this reason, with a 50-mule train, there would be about 8 mules carrying corn and camp-equipage. The consumption of corn averaged from 4 to 6 litres per day per mule, this being divided into a morning and an evening feed. During the 16 months the price paid for corn delivered at supply-points was from \$5 to \$7 per *carga* of 2 hectolitres. Besides the company's mules, a large number of outside pack-trains were employed, as well as numerous burro-trains carrying the lighter stuff, such as cement.

The loads are generally referred to as *carga*, meaning two or more packages weighing up to 150 or 160 lb. each, and *cuarteo*, a piece which by reason either of weight or bulk can only be handled singly. In selecting the *carga* or *cuarteo* for the mule, or the mule for a given load, in one case, the excessive weight would be the predominating factor, in another the bulk, shape of the piece, and difficulties of balancing the load on the saddle. For example, in one of the illustrations is shown a load consisting of pump pinion-shaft with pulley and pinion attached. Mules which are broken to the *carga* cannot well handle *cuarteos*, and vice versa, because of the difficulty of balancing. We have seen mules which could readily handle a *carga* of 420 lb., stumble and flounder about and wear themselves out with a *cuarteo* of 250 lb. Hence, it is advisable to select the mules for each class of service.

Mules broken to carry timber are not effective on other work, and so on. A good *arriero* will almost instinctively select the load best suited to the mule, and will also balance the load perfectly. If this be not done, many mules will be ruined in short order. It pays to be ready to help the Mexican *arrieros*, if you find them in difficulty on the trail, because in

trouble, they are perfectly willing to sit down for weeks, not valuing time nor appreciating the need of rushing things. One difficult matter in handling such a large number of pieces, and packages, and so large a variety of parts, was to have the material forwarded in the sequence of erection. It was no easy matter to identify a given part because of the sectionalization. This was largely overcome by

Timber Transport.

painting with conspicuous colors the pieces as required.

The freight rate for an ordinary *carga*, namely, two pieces, weighing 138 kg. (304 lb.) from Durango to Ventanas, fluctuates between \$4.25 and \$6 per *carga*, or between \$29.25 or \$42 per metric ton, an approximate average cost of \$32.80 per short ton; while, for individual pieces weighing up to 425 lb., that is, *cuarteos*, a special charge of from \$10 to \$100 is made. The railroad rate from any centre in the United States to Durango is \$1.60 per 100 lb. or \$32

Section of Shaft for Mine Hoist; Weight 480 Lb.

per short ton. Add to this the local expenses for discharging, transferring, re-packing, etc. (another \$2 per ton), and the respectable total of \$66 per ton is reached, besides the duties. From Mazatlán the facilities were not so good; but we had only a small part of our stuff to transport from there. The rate from Mazatlán is \$1.60 per 100 lb., and the ocean rate to that port from San Francisco is \$5 per ton. There is no reason why San Francisco should not obtain all the West Coast business, particularly now with the Cananea, Rio Yaqui & Pacific branch of the

Southern Pacific railroad practically exploiting the interior by way of Guadalajara, freight could be handled by boat to Mazatlán or Manzanillo, and thence by rail to the interior.

About 2500 tons of material (1500 tons of machinery, and 1000 tons of supplies and stores) were transported during a period of 16 months. A small part, as already stated, came by way of Mazatlán. It made 17,500 mule-loads, or 262,500 mule-load days, taking 15 days for the round trip. Out of this lot, but 4 pieces of castings were broken, 1 motor-rotor, and 10 tank-sheets lost (out of 2500 sheets). There were 12 packages or pieces lost by the railroads. There were but two pieces of the plant which were not delivered at Ventanas, namely, the bed-plates, with guides cast on, of a Deane horizontal duplex pump, weighing 720 lb. each. These were sent by mistake, and were taken within 10 hours of Ven-

Pump Pinion-Shaft With Pulley and Pinion Attached.

tanias, before the properly sectionalized bed-plates arrived and the mistake was discovered. There they no doubt will remain for a long time as monuments commemorating those gallant mules.

According to the Geological Survey reports, the bauxite industry in 1908 was still suffering from the effects of the depression of the preceding year. The production for 1908 was 52,167 long tons, valued at \$263,968, a reduction of about 47% in quantity and 45% in value. Little or no prospecting or development work was done, despite the fact that numerous new deposits were discovered. The list of producing States is still restricted to Alabama, Arkansas, Georgia, and Tennessee. As in the past, Arkansas leads, producing more than 60% of the total, and this notwithstanding a decrease of about 43% in its production. In Tennessee only one firm is engaged in bauxite mining.

In both quantity and value of output the United States stands at the head of the salt-producing countries of the world.

FOREST SERVICE AND MINING CLAIMS.

The relations of the Forest Service to miners has been productive of much friction. Following numerous protests made by the miners, the American Mining Congress appointed a committee to confer with Gifford Pinchot, Chief Forester. Two conferences were held, on March 15 and March 18 of this year. The outcome of the action of the latter is set forth in the following letter just received by the Mining Congress from Mr. Pinchot. It will be noted that Mr. Pinchot states that efforts will be made to develop a plan whereby the restrictions of the Forest Service will cause no injustice to any mining man. As further conferences will be held with Mr. Pinchot by the Mining Congress committee, those who find any of the regulations of the Forest Service inequitable should communicate at once with the American Mining Congress Forestry Committee, Denver, Colorado.

Gentlemen:

Following what was to me our most promising conference at Denver, upon my return to Washington I have taken up with the legal officers of the Forest Service, as I told you I would do, the preamble and resolutions adopted by the Forestry Committee of the American Mining Congress, which we discussed in Denver, March 18. These resolutions contain two principal statements. The first in importance is:

"That we highly appreciate the courtesy received and the consideration given us to our arguments at the recent conference on the 15th inst., and the prompt compliance with our request for a modification of the ruling and the practice in regard to the examination of and reports upon claims for which application for patent has been made, and wish to express our entire satisfaction with such modification, which we understand to be, that mining claims in any National Forest apparently valid, and held in good faith for mining purposes will not be further examined unless the passage thereof to patent would be prejudicial to the interests of the Government if the said claim should in fact be found to be invalid. No claim will be protested except upon a report by a qualified mining man which gives facts which tend to show the invalidity of the claim.

One of the objects which both your Committee and the Forest Service is most anxious to attain, as I understand it, is to minimize the necessity for having Forest officers consider the validity of mining claims in making statement of fact to the Department of the Interior. Accordingly, I propose to modify the rule in execution of that part of your resolutions just quoted so as to make it read as follows:

Mining claims in any National Forest apparently held in good faith for mining purposes will not be further examined unless the passage thereof to patent would be prejudicial to the interests of the Government if the said claims should in fact be found to be invalid. If any such claim is apparently not held in good faith for mining purposes, it will be examined by a qualified mining expert to ascertain the true condition, and the report of such mining expert will be submitted to the Department of the Interior for its consideration.

This rule goes even further than the agreement reached in Denver, and will, I believe, meet with the approval and support of all legitimate miners.

The second statement of the resolutions is:

"A ruling of the Department of the Interior which is being enforced by the U. S. Forestry Bureau prohibits the claim owner from taking timber from a valid lode claim location for the improvement and development of another claim in the same group is, in the opinion of the Committee, contrary to the spirit and intent of the law, and the cause of much of the friction and dispute between the legitimate mining interest and the Forestry Bureau, and its enforcement entirely prohibits many from developing legitimate mining claims, and works undue hardship and irreparable injury to many others."

The rule to which your resolution refers is one made under authority of the Secretary of Agriculture, and not by the Secretary of the Interior, as I myself supposed and told you in Denver. When the National Forests were in charge of the Department of the Interior, such a ruling was made, and the Secretary of Agriculture followed it when the Forests were transferred to his care. A contrary rule obtains for unreserved lands. I do not believe, however, that it would be wise for the Forest Service to adopt for reserved lands the ruling of the Department of the Interior applicable to unreserved lands, which permits the owner of a group of valid claims to take timber from any claim of the group for use on another claim. The adoption of the rule you propose would require constant determination by Forest officers of the validity of the claims from which timber is cut, and that is just what we most wish to avoid. Furthermore, it could, in my judgment, have the effect of offering a premium on the timber as a temptation to locate claims not valid in themselves, and so would lead to never-ceasing conflict, and thus to the perpetuation or even aggravation of the very conditions we are seeking to avoid. No plan which multiplies the chances for trouble can be satisfactory.

But the Act of June 4, 1897, contains a provision which authorizes the Forest Service to grant free-use permits to miners, and I believe that the necessary immediate relief can be given by a liberal administration of that portion of the act.

The holder of a mining claim in a National Forest has the right to take timber from that claim for use thereon, or elsewhere, if such timber is used for the development of the claim from which it is cut. The regulations and instructions of the Forest Service (pages 70-75, Use Book of 1908) concerning the free-use of timber on National Forests provide that timber to the amount of \$20 in value can be secured from a ranger, and a supervisor can grant free use to \$100 in value. And since the District Forester on December 1, 1908, became invested with the powers given the Forester by Regulation No. 23, such District Forester may now grant free use when necessary for amounts in excess of \$100.

The Service desires that men engaged in prospecting or developing mining claims in the National Forests should have a liberal free use of timber from the Forests, if the timber on any claim is not sufficient for its development, so long as it is a prospect and

not a producing mine. When a prospect becomes a mine and begins to produce ore, it is then a commercial enterprise and no more entitled to free use of Government timber than any other business. This policy will be followed in the administration of the National Forests, and a conveniently accessible and permanent supply of timber for mining will be provided whenever practicable.

I believe that the free-use regulations of the Forest Service can be improved, and for that purpose I will at once issue the following additional instructions:

“In granting free-use permits, Forest officers should make every effort to provide, without unfairness to other interests entitled to consideration, and without injury to the Forest, that no prospector or miner working for the preliminary development or exploration of his claim shall be denied the free use of timber needed and suitable for these purposes within reasonable limits, if there is not upon the claim to be developed a sufficient amount of timber for such uses. Care should also be taken to avoid the marking for use under a free-use permit of any timber which cannot be used by a prospector or miner, or any small user to whom a free-use permit is issued. Large users of special material who operate, or can operate, saw-mills may properly be required to take with such special material other merchantable timber which it is necessary to remove for the future productiveness of the Forest or to avoid rendering the remaining timber on the area unmerchantable. But it is believed that very few cases will arise which will make the enforcement of this restriction necessary as to free-use permits.”

I hope that these new instructions will remove any possible doubt as to the friendly interest of the Forest Service in the mining industry.

I am sure your Committee is considering carefully the difficulties on both sides of the situation we have discussed, and fully realizes that the problem we are endeavoring to solve presents difficulties on both sides. I think you will agree with me that the necessity for examination of the validity of mining claims prior to application for patent should be eliminated as far as possible; and that everything in reason should be done to facilitate the efforts of the prospector and miner to open up and develop the mineral wealth within the National Forests. At the same time—and the Mining Congress has always been in hearty accord with this policy—the National Forests safeguard the welfare of many other interests, and have an important function in the upbuilding of the Western country. Therefore, they should be protected against injury, through mining claims or otherwise. That is what we all desire.

The Forest Service will be glad to co-operate with you in an effort to develop a plan, as nearly as possible automatic in its operation, which will prevent injustice of any kind. An extended examination along this line will be made during the coming summer by the Service, and the result of it will be laid before you in the fall. In the meantime I believe we may congratulate ourselves that real progress has been made. Very sincerely yours,

(Signed) GIFFORD PINCHOL, Forester.

MUREX MAGNETIC CONCENTRATION
PROCESS.

*A new method of wet concentration which has been attracting the attention of the English metallurgists has been brought out by the Murex Magnetic Co., Ltd. It has reached the stage where it is prepared to negotiate for building working plants.

The process is divided into two parts: first, the separation of mineral from gangue, and second, the separation of mixed minerals from each other. The crushed ore is treated with a solution, mixed with a small quantity of water, and then passed under a single magnet. The recovery of mineral thus obtained is said to be exceedingly complete. The solution is then removed, and in the case of an ore containing only one or two minerals, such as lead and silver, which do not require further separation, the operation is at an end. Where a further separation is required (for instance, in a mineral containing lead and zinc), a second operation is necessary, as follows: no re-crushing is required, but the concentrate, after being dried, is mixed with a small percentage of the Murex solution and passed over ordinary concentrating appliances, whereby the different minerals are separated from each other. The quantity of middling required for re-treatment is a small percentage of the whole. The treatment of the slime presents no difficulties, and the ‘float’ is obviated. The solution which renders the minerals susceptible to such separation is called a ‘magnetic solution’. The Murex Magnetic Co.’s process gives a magnetic property to the original minerals in the ore by adding a small percentage of magnetite and extracting, by means of a magnet, the added magnetite along with the original minerals, thus solving the problem.

A test on a low-grade Broken Hill ore, the weights and assays of which were taken by Arthur Claudet, gave the following results:

	Lead. %.	Zinc, %.	Silver, oz. per ton.
Crude ore	14.50	12.80	9.00
Lead concentrate	73.00	3.50	29.20
Zinc concentrate	5.60	44.00	8.20
Tailing	1.70	3.30	1.80

As no recovery of the zinc is at present obtained from this ore, the whole of it may be considered as additional value obtained. On this basis, the additional gross value of the recoveries in marketable products in favor of the Murex process, with lead at £13 per ton, spelter £20 per ton, and silver 26d. per oz., over the values recovered by the present treatment is as follows:

	Per ton of crude ore.
In silver—lead concentrate equal to	4s 4d
In silver—zinc concentrate equal to	5s 7d
Total	9s 11d

The Murex Magnetic Co., Ltd., owns the process for the United Kingdom, the Colonies, Germany, and Austria. The directors are the Hon. Lionel Holland, W. C. Bond, Alex. Stewart, Frank Owen, and Marcus A. Samuel. The manager is Julius Buss, and the consulting chemist Edouard Heberlein.

*Abstract from the Financial Times.

DREDGING INDUSTRY IN NEW ZEALAND.

By ARTHUR C. BUCKLAND.

*Although New Zealand has led the way in the gold dredging industry until the present time, she is in danger of losing her position of proud pre-eminence. We have dredges in New Zealand that look more like heaps of scrap-iron than anything else; we have also mammoth machines, like the Earnsclough No. 3, whose buckets have a capacity of 7 cu. ft., whose pontoons are 132 ft. in length, in beam 30 ft. and 7 ft. in depth. Her ladder permits dredging to 50 ft., and carries buckets of 7 cu. ft. capacity, while her tailing elevator stacks the tailing to a height of 70 ft. The fleet numbers over 200 dredges. With an average of 8 to each dredge, over 1500 men are directly employed. The annual coal consumption is estimated at 100,000 tons. This means many miners, and if we include the foundry work necessary, the number of men directly and indirectly employed by the dredging industry will approach 3000. All sorts and conditions of ships go to make up the fleet, and all sorts and conditions of machinery and engines may be found in them.

The laws guard as far as possible against accident on a dredge. Machinery guards must be in place, a stoppage must be made while oiling up, life-lines, life-belts, boats, boat-hooks, must all be provided, kept in good order, and placed in accessible positions. It is compulsory to have a first-class certified engineer in charge of the boiler and engine. Inspectors come around to see that these requirements are duly complied with.

The cost of a large new dredge is from £13,000 to £14,000, but dredges are frequently purchased and put to work for one-fourth that sum. Frequently land is worked on a royalty basis, but usually it is bought in 5-acre lots. During the boom in dredging the areas taken up were too small, and too many dredges were put to work side by side. Consequently nearly every dredge passed into liquidators' hands sooner or later and was put up at auction. Usually such dredges are eagerly snapped up by small working parties, who make them pay very well. The reason is that they are content with a fair wage each out of the returns. Suppose 4 men take over the dredge, they will think themselves well paid at £4 weekly each. A dredge that has given returns of 8 or 9 oz. per week will, of course, never pay dividends on some thousands of shares; but such ground will suit small working parties very well. When once the dredge has been repaired, they have no expenses except for coal. No secretary is required, and there are no directors' fees. In this manner dredge after dredge is dropping into the hands of the working parties; and in most districts it is only a matter of time before the large company with 10,000 shares, directors, and secretary will be a thing of the past.

There are many untried areas left in New Zealand. It appears as if the dredging had, with painful lack of originality, until now merely tried the vicinity of the old-time gold rushes. Dredges are with few

exceptions found round about those areas that were richly auriferous and mostly worked out in the sixties. Such places are the Clutha river and its tributaries, the West Coast Provinces, Waipori, Switzers, Lawrence, in the South Island. It will be a good day for mining when systematic prospecting is carried on over some of the untried ground. This is in places somewhat difficult of access, such as Southland. In Otago there are at present about 100 dredges at work, in Southland 50, on the West Coast 40, and one can add a few that are working in Nelson and Marlborough.

The wages paid have to a great extent been settled by an arbitration court. Strikes in New Zealand are illegal. On any dispute arising as to wages, the matter must be referred to the arbitration court, which then fixes the wage for the district. In the more accessible districts this is at the rate of 8s. per shift of 8 hours for firemen and winchmen, while where living is dear, in out of the way spots, the wages rise to 9s., and in others to 10s. per 8-hr. shift. Overtime is in all cases paid at the rate of time and a quarter for week-days, and double pay for Sundays. The engineer receives from £3 to £5, the dredge-master £4 to £6.

As things are at present, dredging can scarcely be looked upon as a permanent industry. In time to come, however, larger dredges and improved gold saving appliances will result in the working of areas that are at present doubtful investments. Fortunately, the old plan of dumping a dredge onto a block of ground preceded by scarcely any reliable tests is now very rare. Boring is coming much into vogue in prospecting, especially where heavy drainage will not permit shaft sinking. Most of our dredges are turning over ground about 30 ft. at the most in depth, so that a hand-labor boring plant is quite able to give the ground the necessary trial.

In the Rocky Mountain States—Colorado, Idaho, Montana, New Mexico, North Dakota, Utah, and Wyoming, the output of coal in 1908, according to the Geological Survey, amounted to 21,684,414 short tons, valued at \$33,252,730. In 1907 the production in these States was 23,990,917 short tons, valued at \$36,097,789. In not one of these States did the production in 1908 exceed that of the preceding year. The total decrease amounted to 2,306,503 tons; the decline in value was \$2,845,059. Almost exactly 50% of this decrease in production occurred in Colorado, whose output declined 1,155,263 short tons. Nearly 40%, or 763,839 tons, was in the output of Wyoming. These two States, Colorado and Wyoming, contribute more than two-thirds of the total production of the Rocky Mountain region. The Pacific Coast States, which include the Territory of Alaska and the States of California, Oregon, and Washington, in 1908 produced 3,123,468 short tons of coal, valued at \$6,976,332, against 3,775,602 short tons, valued at \$7,937,918 in 1907, a decrease in production of 652,134 short tons in quantity and of \$961,586 in value. In California and Oregon there were small increases in production, but in Alaska and in Washington the production decreased. Of the total production in the Pacific Coast States, 97% is from Washington.

AGITATOR FOR CYANIDE TESTS.

Written for the MINING AND SCIENTIFIC PRESS
By G. H. CLEVENGER.

After designing and using several types of agitators, for making small cyanide tests, the writer has found that the machine herewith illustrated is the most convenient and satisfactory in every respect. It may be readily constructed in any mine-shop of ordinary equipment.

It will be noted that the machine is simply a series

Agitator for Cyanide Tests.

of large wooden rollers mounted upon a table or other suitable base. Large 2½-litre acid bottles are used as containers for the pulp; these are not filled over one-third full, or so that the pulp does not run out at the necks of the bottles when they are lying on their sides upon the rollers. By this method the agitation is effected in open bottles, and the annoyance of inserting corks is avoided. The test is made under conditions resembling treatment in an open tank. The wooden rollers are reinforced at their

Dimensions of Agitator.

ends by means of iron bands; these serve the further purpose of preventing the bottles from working off at the ends of the rollers. Two idle rollers may be successfully used upon each side of the driven roller. Increased capacity may be obtained by making the rollers longer. Any source of power may be used, but for an agitator of moderate size, a small electric motor will be generally found to be the most satisfactory. The driven roller should run at a speed of 30 to 50 revolutions per minute. At first, until the bearings become limbered up, it may be found necessary to place a couple of heavy rubber bands upon each bottle, in order to get the necessary friction for driving the idle rollers. Re-grinding tests may be readily made with this agitator, by filling the bottles

about one-third full of small glass marbles, before adding the ore and solution. In this case it is best to use corks, which should be carefully attached.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

A. C. R., California: Specular hematite.

J. R. H., Alamos, Sonora, Mexico: Sphalerite.

W. E. C., California: Quartz schist with pyrite.

F. H. M., Johnson, Arizona: No. 1, a tuff, most probably andesite tuff; No. 2, acid andesite, or trachyte; No. 3, andesite charged with hematite.

O. B. A., White Hills, Arizona: No. 1, granite; No. 2, a garnet-quartz aggregate—a contact rock; No. 3, metamorphosed andesite; No. 4, quartzite; No. 5, diorite-porphyrity; No. 6, a dense fine-grained black trap, probably of the diorite family; No. 7, metamorphosed andesite; No. 8, weathered acid andesite; No. 9, porphyritic andesite, much metamorphosed; No. 10, porphyritic andesite, much altered; No. 11, indurated shale; No. 12, andesite.

J. H. H., Etzatlan, Jalisco, Mexico: No. 1, a somewhat decomposed rock, intermediate in character between diorite-porphyrity and andesite; it shows a slight content of hematite; No. 2, a metamorphosed basic rock, probably of the gabbro series, with fine-grained porphyritic texture; No. 11, a very fine-grained aggregate of galena, chalcopryite, and possibly sphalerite, in quartz; No. 21, andesite; No. 24, quartz porphyry; No. 25, aggregate of galena and sphalerite; No. 26, andesite or basalt pebble with extreme surface weathering.

Sand-lime brick produced in the United States in 1908 had a total value of \$961,226 and represented the output of 87 plants. In 1907 the output was valued at \$1,225,769 and was furnished by 94 plants. The net decrease in the value of the output in 1908 was therefore \$264,543. The average price per thousand received for common brick of this character in 1908 was \$6.33, as compared with \$6.61 in 1907 and \$6.71 in 1906; for front brick the average price was \$12.76 in 1908, as against \$10.96 in 1907 and \$10.42 in 1906. It is apparent, therefore, that while common brick has decreased in price, front brick has increased. A report on the condition of the sand-lime brick industry in 1908 will be published by the U. S. Geological Survey shortly.

NATURE OF GOLD IN ALLUVIALS.

Written for the MINING AND SCIENTIFIC PRESS
By F. LYNWOOD GARRISON.

The nature and process of accumulation of gold in alluvial deposits is a matter of practical importance of some scientific interest, and the subject is by no means as simple as may appear at first sight. That alluvial gold is a product of erosion derived from auriferous veins in neighboring hills and mountains is obvious. In many cases it is evident that the gold has been carried long distances from its source, especially when of a flaky character, which increases its suspensibility in water, and lessens the natural concentration tendency due to its great specific gravity. But the assumption that all alluvial gold is derived solely by erosion cannot be accepted as conclusively proved. Doubtless by far the greater part is thus accumulated, but there are evidences that a considerable amount of gold in alluvials may be due to precipitation from solutions as a chemical deposit. The rate or degree of this chemical deposition varies, and is affected or regulated by natural conditions, such as rainfall, evaporation or dryness of the air, temperature, grade of the streams, and the solubility of the gold as it existed in the rock deposits from which it was primarily derived. The character of the underground circulation is no doubt also an important factor, some waters carrying more alkaline or gaseous compounds than others, hence we have a dissolving power proportional to the content of the particular constituents that have a solvent effect upon gold. Thus, for example, water containing an appreciable quantity of the haloid salts will dissolve gold more readily than pure water. Louis thinks that gold is introduced into the deposits as an alkaline aurate and not as a soluble haloid salt.¹

It may at first sight seem like thrashing out old straw to re-open this subject, but the more one considers it the more evident is it that a number of unsolved problems are involved. Twenty-five or thirty years ago the chemical deposition of gold in alluvials was extensively discussed by chemists and geologists, notably by Egleston, Selwyn, Lieber, Genth, Becker, and Doelter, and in later years, by Henry Louis and H. A. Gordon. The latter, in his paper on the 'Hysteromorphous Auriferous Deposits in New Zealand',² reviews the literature on the subject, and draws some valuable conclusions therefrom. Although the published investigations by the persons mentioned do not clearly so indicate, it is evident that they are satisfied with the soundness of the chemical hypothesis. Notwithstanding this fact, there appears to be at present a disposition to discredit all chemical deposition theories, objections being based apparently upon no substantial ground. Among a number of unexplained or but partly explained facts observed in connection with the study of alluvial gold deposits, may be mentioned the following:

1. The gold in alluvials is always purer than the

average fineness of the gold in the neighboring vein-deposits; moreover, it seems to be a general rule that the minute particles of gold always contain less silver than the accompanying coarse particles. The grade of purity of placer gold is often assumed to conform in a general way to that of the original vein-gold; this is not correct, for it is indisputable that some of the silver alloyed with the primitive gold in the veins disappears as the gold is comminuted by attrition in the gravel.

2. Gold is sometimes found as nuggets and small particles in rocks which have never been moved by erosion from their original positions, but which have been decomposed to a considerable extent. Gold particles under such conditions are usually free or semi-detached in the decomposed material, the assumption being that such nuggets and particles were formed in place in the decomposing rock or vein-matter.

3. Veins carrying gold, especially auriferous copper deposits, are nearly always richer in gold near the outcrop, indicating that the more soluble copper minerals were dissolved with the weathering of the vein, leaving the gold behind. Subsequent erosion would of course carry these particles down into the stream beds, forming alluvial gold deposits or placers.

4. There is apparently no relative proportion between the richness of the alluvials and the richness of the neighboring vein-deposits. Some of the most productive alluvial gold mining districts in the world show few evidences of quartz deposits of sufficient size and richness to pay to mine under ordinary conditions. At first sight it might be supposed that rich alluvials must consequently have rich sources of origin, considered in a commercial sense, but this fact does not necessarily follow, since nature draws its stores of rich alluvial gold from innumerable small vein-deposits as well as from the country rock itself, concentrating the particles through long ages in the stream gravels and river bars. In this connection it is well to bear in mind that gold is not a rare metal, it is, in fact, a common one in certain districts, but in its primary condition it is widely scattered in minute quantities.

Concentration in veins and other lode deposits, through the agency of gases and the hot and cold solutions of the underground circulation, may be considered the first great stage in the formation of gold deposits. Accumulation by erosion and concentration in stream-beds and other alluvial deposits being the second and probably final condition. In California, as in the Nome and Yukon districts of the North, it has been the alluvials that have established the reputation of the districts, and not the lode deposits, which as a rule have been disappointing or wholly unprofitable. Other instances in different parts of the world can be adduced to illustrate this point. Indeed, even the great lodes that have made South Africa the greatest gold-producing region in the world are primarily of alluvial or sedimentary origin. It is true that the blanket, or gold-yielding conglomerate of this region, is accompanied by eruptive dikes, which some geologists assume to have been the source of the gold, but the consensus of opinion ap-

¹*Mineral. Mag.*, Vol. X, No. 47, p. 241. *Trans. A. I. M. E.*, Vol. XXIV (1894), p. 186.

²*Trans. A. I. M. E.*, Vol. XXV (1895), p. 292.

pears to favor its essentially sedimentary origin. The conglomerate in which it occurs was certainly derived by erosion, and the gold and pyrite which is closely associated with the conglomerate is rarely or never found in the quartz-pebbles composing it, but only in the surrounding cementing mass that binds these pebbles into a hard rock.

5. Whenever pyrite occurs in auriferous gravels, it invariably carries gold. Pyrite is not infrequently found deposited upon buried logs and tree-branches, thus showing the action of organic matter in precipitating iron sulphide and its associated gold under natural conditions.

The probability that gold is soluble in meteoric and underground waters may be safely conceded, and that it is precipitated by the action of organic matter is an accepted fact, but that it is in solution in sufficient quantity in the waters flowing through alluvial deposits to add appreciably in this manner to the gold accumulation in these gravels, is not so plain. It appears certain that beds which contain much organic matter are apt to be especially rich in gold. Solution takes place with great slowness, as does precipitation, hence the period of time necessary to transfer any great amount of gold by such means, as compared with that required to transfer it by the active mechanical processes of erosion and concentration, must be enormous. The actual importance of the chemical influences will depend upon and vary under different conditions and places, as, for example, the character and nature of the percolating waters, the presence of materials in solution capable of bringing about a precipitation of the gold, and the length of time during which these processes have had an opportunity to act. It is evident, therefore, that the importance of mechanical is vastly greater than that of chemical concentration. According to Spurr, chemical processes have had little to do with the concentration of gold in the Alaskan gravels. "The metal occurs in regular flat scales, like those which are found filling the cracks in quartz veins, and in a mammillary form, suggesting that deposition from solution has not been noted. The flat forms are best seen in the smallest grains, the larger masses having been generally somewhat rounded by contact with harder bodies, moreover the gold from the smallest to the largest fragments is often mixed with vein-quartz in all proportions, in such a manner as to leave no doubt as to the detrital origin of both."¹

Egleston thinks that when the action is localized and slow we have placers with nuggets and irregularly shaped pieces, and when it is rapid we find the gold with small particles distributed through the sand. The same conditions which cause solution of gold in certain cases cause also the solution of silica. This explains the phenomenon of mammillary and apparently water-worn nuggets encased in quartz, while both the gold and quartz have been formed later than the gravel. Many causes which produce the precipitation of gold would also cause the reduction of soluble sulphates into insoluble sulphides, the gold being retained in the latter. This would ac-

count for the almost constant presence of gold in pyrite.

The experiments of Becker⁴ and Doelter⁵ on these points are most interesting and informing, and indicate that heat, and perhaps also pressure, increase the solubility. At this point it is desirable to call attention to observations of Liversidge upon the concentric character of some gold nuggets from New Guinea. The usual macro-crystalline structure is absent in these nuggets, and toward the edges a clearly marked concentric condition is manifested.⁶ These two nuggets weighed 0.90 and 0.86 oz. respectively, and were found on assaying to be 889 and 882 parts fine, the associated metal being silver. When sliced, polished, and etched with aqua regia, small enclosures of hematite and quartz and also cracks and cavities became visible, but the usual amorphous structure was absent. Parts near the edges showed clearly marked concentric lines.

It is evident from these data that gold in alluvials is susceptible to some accretion by chemical precipitation, but it is certainly slight, and no one is justified in concluding from this fact that old and worked-out placers could appreciably enrich themselves within periods of time included within human history. The valleys of the tributaries of the Po in Italy, the rivers of the Central Plateau of France, and the Rhine in Germany produced gold from alluvial washings in the time of the Roman Empire, but probably they would not now pay to work, even with the most improved appliances. When both mechanical and chemical accretion has failed, as in these cases, to substantially enrich the river-gravels in a thousand years, the degree of accumulation must be exceedingly small, although of course it is well known that none of these streams drain notable gold-producing rock-areas. Mechanical accumulation of gold on river-bars after floods is, on the other hand, frequently rapid. In many gold-producing countries the bars have been worked by the natives year after year from time immemorial. They are not exhausted because the annual freshets deposit upon them a new supply of gold. This will continue as long as the sources of the gold at the head-waters of the streams are productive. In China certain streams have been worked for hundreds, or perhaps thousands of years, and still yield a profit to the patient frugal Chinaman, from gravels that would be considered by others too poor to work with the best equipped dredge under favorable conditions. This statement probably deserves some qualification, as it has been some years since the writer was in China, and the dredging art has taken great strides within that time, but the general principle enunciated is not changed.

The question of gold-accretion, both mechanical and chemical, in existing streams, is a subject worthy of thorough study, and must be taken up in the near future as our gold resources from new territory become more and more exhausted. The future source of gold supply for civilization's rapidly growing

⁵*Jour. and Proc. Royal Soc., New South Wales*, Vol. XL, p. 161.

needs is by no means sure, even for the next 50 years. Far be it from me to become an alarmist on this subject, but much thought, wide reading, and not a little travel have forced me to this conclusion. It is becoming more evident that gold will become dearer in its relation to food, notwithstanding a tremendous increase in its production. Doubtless many partly exhausted alluvial deposits can be profitably re-worked with our steadily improving mechanical appliances, especially with dredges, but the extent of territory that may be profitably dredged is becoming more and more restricted each year, and sometimes one is disposed to conclude that where the conditions for the practice of this art are favorable the areas suitable never have been and never will be found to be extensive.

It has been remarked by Posepny that the concentration of gold at the base of placers during the time of their deposition as fluvial accumulations, cannot be easily explained. A natural settling process we are not justified in assuming, for the reason that the material of the placers usually shows no indication of a sorting or classification of its material, but on the contrary is composed throughout of particles varying greatly in size and weight. In fact the loose débris forming a placer was not all at once moved or even stirred by the water, but was deposited at different periods, layer upon layer.⁷ Posepny considers that concentration of the gold on the bedrock took place after the deposition of the gravel by a simple mechanical slipping downward of the gold particles, with the aid of water, through the interstices of the gravel, just as in the case of pulp left standing for a considerable period, and also in piles of mixed ore, even when undisturbed, it is found that the galena tends to settle and accumulate at the bottom. This, however, does not explain the condition satisfactorily, for frequently, if not in most cases, the gold is concentrated in streaks or layers that are often many feet above the bedrock, and there are frequently several such layers. This is true of old gravel benches or deposits, as well as of those in existing streams. Moreover, they are sometimes richer in gold than the gravel resting directly upon the bedrock. The question appears to be an enigma the probable explanation of which is to be sought in the currents of the streams depositing the gravel.

Rustiness of gold⁸ Louis considers to be due to a number of different causes. That there is more than one kind of rustiness seems certain, and we are warranted in classing allotropism among its causes. It has long been well known that rusty gold is indifferent to mercury, and that it is often the cause of great losses in mining and metallurgical operations; hence the question is of large practical importance. I have been recently examining microscopically some rusty gold collected from the placers of the Cauca valley, Colombia, South America. I have found in this instance that the rustiness appears to be of two kinds, a black stain on some of the particles of gold,

and upon others from the same deposit a dull reddish color. When treated with hydrochloric acid the black stains disappear immediately, whereas the dull reddish color is not appreciably affected by the acid, but sometimes completely detaches itself as a film from the gold particle and floats off in the solution. Under the microscope this exceedingly thin pellicle or skin looks like gold by reflected light, but by transmitted light it fails to give the characteristic greenish color peculiar to gold under such conditions, and it has a reddish color. Some of these gold-grains which I have examined are surrounded by a matrix of minute quartz particles cemented together and to the gold by iron oxide. In the great majority of instances the rust is undoubtedly due to iron oxide, and in tracing back to the deposits from which these particular gold-particles came, it was found that they are old bench-gravels undergoing considerable decomposition.

In wet, tropical countries the extent of rock decomposition in place is usually enormous, and results in thick accumulations of argillaceous and ferruginous residues, known variously as laterite, cascajo, *roche à ravets*, and saprolite.⁹ The damp heat of the tropics, aided by decomposing vegetation, is a very powerful agent of alteration and of consequently chemical enrichment. According to Levat,¹⁰ the *roche à ravets* of French Guiana often contains besides microscopic particles of gold, nuggets, often so completely covered with a ferruginous coating as to be taken for blocks of iron oxide. No one who has been practically engaged in mining in moist, tropical countries could fail to have noted the intensity of rock-decomposition where covered with forest or jungle; it exceeds as a rule any similar conditions to be found in temperate or frigid regions. Frost cannot play much part as an active disintegrating agent below a few feet in depth, and the effect of differences in temperature between day and night, a most potent agent in arid regions, is not appreciable at depths of even a few inches below the top soil. Hence it would seem that to organic acids from the moist, over-lying vegetation we must ascribe the energetic corrosive action upon rocks so evident in tropical countries. This force is naturally active upon gravel deposits and its decomposing, disintegrating power is relatively rapid and effective, breaking up the feldspars, dissolving the iron, reducing the ferric to ferrous sulphate, which must have some precipitating action upon any gold in solution. Later the ferrous salts are converted to ferric oxide, which is often found as a cementing and binding material in the manner aforesaid.

⁷Zur Genesis der Metallseifen, Oesterr. Zeit. f. Berg. & Hüttenw., 1887, Vol. XXXV, p. 325. Also Trans. A. I. M. E., Vol. XXIII (1894), p. 337.

⁸Op. Cit., p. 186.

⁹Geo. F. Becker, 16 Ann. Rep., U. S. Geol. Sur., Part 3, p. 284. The word saprolite is used by Becker to signify a thoroughly decomposed rock in place. Laterite is a synonymous term, used in India, where it originated, but he objects to it on the ground that it also applies to transported material, and this is true. Just why the simple term 'decomposed country rock' is not good enough for the purpose he does not make clear; the interjection of new and unnecessary technical terms into scientific or pseudo-scientific literature should be avoided where plain English expressions will serve quite as well.—F. L. G.

COMPANY REPORTS.

UTAH COPPER.

The report of the Utah Copper Co. on its operations at Bingham, Utah, for the first quarter of 1909 shows that as a result of inadequate transportation the tonnage mined and milled during January and February was below the capacity of the plants, and the earnings were correspondingly small. Transportation conditions improved materially in March, however, and the milling capacity of the plants was approached. The total tonnage for the quarter was approximately the same as that for the last quarter of 1908. The gross output of copper in concentrate produced was 12,107,549 lb., the excess over the last quarter being 330,885 lb. The cost per pound of copper was slightly higher, being 9.68c. per lb. of net copper produced after deduction of smelter allowances. The average net recovery at the mills improved nearly 5%. A better quality of ore was milled, with less oxidized copper minerals. The average copper content was somewhat lower, so that the net pounds recovered per ton were only slightly greater.

The net profit from mining and milling operations for the quarter amounted to \$375,894. The additional income amounted to \$6574. The total net profit for the quarter was \$382,469. The average price of copper was 12.82c. per pound, less by nearly 1.3c. than for the previous quarter. At the expiration of the period sales of copper had been made covering the output available for delivery well into the month of April, and no stock of finished copper was carried over.

March was the first month in which the total capacity of the plants was approached. More than half the earnings for the entire quarter were made in the one month, on the basis of 12½c. copper.

The tonnage for the month of April, so far, has been somewhat above the rated capacity of the plants, and the output of copper for the month will be considerably in excess of the output for the month of March, which was over 5,000,000 lb. Should this condition continue throughout the second quarter, the earnings should be nearly if not quite double those of the first quarter, at the same prices. The ore treated during the first quarter was 21½% from underground and 78½% from steam-shovels. During the quarter an additional steam-shovel was put into commission on stripping. Nearly 95,000 cu. yd. of capping was moved monthly. During March the removal of capping amounted to over 111,000 cubic yards.

BROKEN HILL PROPRIETARY.

The report of the Broken Hill Proprietary Co. on operations at their mines in New South Wales, for the half-year ending November 30, 1908, shows, despite labor troubles, a net profit of £25,791, and liquid assets of £459,729. The production for the half-year amounted to 264,847 tons. The zinc concentration plant handled 135,235 tons, producing 29,659 tons of concentrate, assaying, zinc 44.09%, lead 9.60, silver 14.88 oz. Strong sulphuric acid to the amount of 2752 tons was made. The Port Pirie lead-smelting plant was operated continuously, handling 125,784 tons of ore, 5915 of dross, and 1280 of dust, producing 48,350 tons of bullion. The Huntington-Heberlein plant is reported to have done good work, the gas-firing giving every satisfaction. The Carmichael-Bradford plant handled 25,683 tons of concentrate. In the refinery 48,368 tons of bullion was handled, yielding 2,589,416 oz. silver, 1054 oz. gold, 47,833 tons soft and 470 antimonial lead. The first zinc distillation furnace was finished and tested. Nine more furnaces are being built.

CLOVERFIELD.

The Cloverfield Mines, Ltd., is the owner of 801 mining claims on the Rand, on the Cloverfield farm. The mine is now being re-opened, shaft-sinking having been resumed last September. The shaft was put down 103 ft., or to 1448 ft., by the end of 1908. S. C. Thomson is consulting engineer.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

PRINCIPLES OF MINING. By Herbert C. Hoover. 8vo., pp. 199, Ill. Hill Publishing Co., New York, 1909. Price \$2.50.

This little volume discusses especially the valuation, organization, and administration of copper, gold, lead, silver, tin, and zinc mines. It is based upon lectures given at Stanford and Columbia Universities. It is written essentially from the point of view of mine valuation. As would be expected from the author's wide experience, it is replete with interesting and valuable data. While no claim is laid to great originality the book is extremely suggestive. Its scope is confessedly limited and much of it more applicable to "deposits of fissure vein type" than to those in which "metals occur like plums in a pudding." Problems of pumping, ventilation, haulage, and hoisting are only discussed in a general way, but with distinct reference to mine valuation. The details of opening up and equipping a mine, as given by Mr. Hoover, afford hints for the examining engineer, reminding him of the elements of the problem. This discussion, while occupying the greater bulk of the volume, is less vital than the opinions on mine valuation offered by a man of such wide experience in connection with properties where large responsibility has been involved. He calls attention to the risks in sampling which ensue from having no means for checking the work by assays made on the spot. Such assays are an invaluable safeguard, though no engineer would depend upon these alone as a basis for his report. Mr. Hoover also reminds us that ore sampled in place commonly gives higher results than subsequent mill-records will sustain. The truth of this statement engineers of experience will confirm. The author cites an example in South Africa where the assay-samples proved to have been too high by 20%. A factor of safety must manifestly be adopted, and Mr. Hoover proposes a minimum of 10% as an appropriate basis for discounting the results of sampling. Manifestly it will vary widely in different mines. His definition of ore according to the state of development of the mine is rational and worthy of universal acceptance. He recognizes four degrees of certainty: (1) positive ore, developed on four sides; (2) ore blocked out, developed on three sides; (3) probable ore, where two sides are exposed; and (4) possible ore, of which but the upper side is open to inspection. The great question of amortization of capital is handled in a manner to impress the reader with the necessity of making adequate provision for re-imbursing the investor, but the speculative features of mining are so strong, and the custom of over-valuation so persistent and universal, that in effect Mr. Hoover has recourse to the general average of success, in spite of insufficiency of demonstrated ore, as a basis for assuming what measure of precaution or of risk a man may take in this regard. He works out interesting and suggestive examples, but a lack of well crystallized advice is conspicuous in this chapter. His one definite declaration of conviction on the point consists in this: "Mining business is one where 7% above provision for capital return is an absolute minimum demanded by the risks inherent in mining." But in determining the purchase price which may be recommended, does Mr. Hoover insist upon seeing the whole of it in 'positive' and 'blocked' ore, or may part of it be assumed to lie in the 'probable' ore, or perchance even in the uncertain depths of 'possible' ore? He meets here the problem that men will not let the engineer solve. The successes following risks, though fewer than the failures, are so conspicuous that the capitalistic world would refuse to follow the engineer who would button him up in a straight-jacket of conservatism, and demand that the ore available for stoping should even possess a gross value equal to the amount of risk involved in its exploitation. The system of working out the value of shares or dividends, certain conditions being postulated, is simple enough, and the exposition given by Mr. Hoover is lucid and important. The great difficulty is in agreement upon what shall constitute the degree of safety required

for the initial investment. As a general law he declares that the speculative value of the 'good-will' in ordinary commerce is greater than in mining. This is probably true. The percentage of commercial failures is certainly greater than the percentage of mine-failures, if we eliminate the disappointments of the prospectors. After all it is a question of averages, a problem participating in the risk that inheres in life itself. But Mr. Hoover does not leave the reader 'in the air'. Without coming to conclusions in dogma, he argues by example and gives impressive illustrations of risks that are manifestly unwarrantable. Between these and theoretical certainty the capitalist and his engineer must elect what they shall consider the prudent mean in each specific case. The volume is the best exposition in existence of the methods by which the modern engineer proceeds to value mines; it represents the opinions of a man who speaks from the ground of vantage of having been himself a part in the conduct of great enterprises from the stage of early uncertainty to the maturity of large success.

MINERS' & SMELTERS' TELEGRAPH CODE. Adopted by The American Smelting & Refining Co. 8vo., pp. 464. The Business Code Co., New York, 1908. Price \$12.

A leading merit of this code consists in its extremely systematic method for the development of a compact expression for a lengthy sentence. In actual use it admits of saying two or three times as much as is possible with other codes in the same number of words. The code-words are to a considerable extent built up by union of so-called phrase-words. Each code-word consists of 5 letters, which are mere combinations of letters arranged in alphabetic order. They do not make true words in any language, but are mere symbols. There is no chance of confusion of one code-word with another, since the phrase unit consists always of the same number of letters. For economy two such units may be joined in transmission. The defect of the system is that the telegraphic operator has no rational basis to assist in correct transmission, and errors arise more frequently than with other ciphers. Its advantages in other respects, however, outweigh this difficulty.

REPORT ON THE EXAMINATION OF SOME IRON ORE DEPOSITS IN THE DISTRICTS OF THUNDER BAY AND RAINY RIVER, PROVINCE OF ONTARIO. By F. Hille. Canadian Department of Mines, Mines Branch. 8vo., pp. 65, Ill. Ottawa, 1908.

INVESTIGATIONS OF THE COALFIELDS OF COLORADO, NEW MEXICO, UTAH, OREGON, AND VIRGINIA IN 1907. By H. S. Gale and others. Bull. No. 341-C, U. S. Geol. Survey. 1909.

CONCRETE-STEEL CAISONS. Their Development and use for Breakwater, Piers, and Revetments. By W. V. Judson. Jour. West. Soc. Eng., advance sheets, pp. 70.

PROGRESS OF THE MINERAL INDUSTRY OF TASMANIA. For the quarter ending December 31, 1908. Compiled by W. H. Wallace. 8vo., pp. 13. Tasmania, 1909.

STATE GEOLOGICAL AND NATURAL HISTORY SURVEY OF CONNECTICUT. Third Biennial Report of the Commissioners. 8vo., pp. 30. Hartford, 1908.

SUMMARY REPORT, GEOLOGICAL SURVEY BRANCH, DEPARTMENT OF MINES. For the year 1908. 8vo., pp. 220. Ottawa, 1909.

It is interesting to note that turbines have been adopted in the plant of the PORTLAND CEMENT Co., at Portland, Colo., for power extension, rather than Corliss engines, two of which have already been operating for a number of years on surface condensers. The fuel used is a southern Colorado bituminous coal of rather poor quality. With the moderate superheat and high vacuum contemplated, it will be possible for the turbine to effect considerable economy in operation. Although direct current is largely used at this plant, an alternating current turbine unit was selected in connection with a rotary converter as providing greater flexibility of operation than obtainable with a direct-current turbine unit which was also under consideration.

New Mining Theodolite.

The accompanying engraving illustrates a new theodolite adapted to mountain and mining work. It has a 4½-in. limb and vertical circle with edge graduation, 8-in. 20-power main telescope, 7-in. 18-power auxiliary telescope (with counterweight) that may be used either as a top or side telescope, 4-in. 30-second telescope level, stadia, gradienter, magnetic variation circle, 4-screw leveling head and extension tripod. The instrument weighs 9 lb. complete with all attachments. It is made of hard bronze alloys, and a 2¼-in. compass for checking is fixed in the centre. The limb verniers are placed at 30° with the line of sight, which, together with the edge graduation on the vertical circle, enables an operator to read both vertical and horizontal angles from the one position. The telescope tubes are so finished as to insure perfect collimation for all distances. High-grade lenses are used. The telescope axis has the usual grooved bearings common to all this firm's instruments.

The leveling head is of improved design, constructed so that it cannot be cramped in any position. This greatly reduces the wear on the leveling screws and renders it unnecessary to loosen all of the screws when leveling up. The shifting centre has a movement of ½ inch to permit placing plumb-bob over point. The graduations, with the exception of the compass circle, are on solid silver. They are produced on the new 30-in. automatic dividing engine belonging to the makers, Wm. Ainsworth & Sons of Denver. This machine, it is claimed, can produce automatically circles accurate to within one second of arc. The instrument is described in their catalogue BX9 just issued.

Catalogues Received.

THE DENVER FIRE CLAY Co., Denver, has just issued a bulletin describing its Iler disc pulverizer, a new machine of the oscillating type.

THE SULLIVAN MACHINERY Co., Chicago, has just published an attractive little booklet describing the different types of Sullivan machines.

THE JOSEPH DIXON CRUCIBLE Co., Jersey City, N. J., is distributing a small booklet giving information regarding its line of graphite products.

THE AMERICAN ELECTRIC FURNACE Co., New York, has recently published a bulletin descriptive of the Rochling-Rohenhauser and ordinary induction furnaces.

FAIRBANKS, MORSE & Co. have just issued a general catalogue covering the complete line of goods carried by that concern. There is included much that is of interest to mining men.

Commercial Paragraphs.

ALBERT W. MCINTIRE has opened law offices at Suite 23-26 Haller Bdg., Seattle, and will devote special attention, for Washington and Alaska, to all phases of mining law.

WALTER B. SNOW, of Boston, Massachusetts, announces the association with his staff of Carl S. Dow, recently publicity manager for B. F. Sturtevant Co., and formerly in charge of instruction and text-book departments, American School of Correspondence.

DWIGHT T. RANDALL, recently engineer in charge of fuel tests, Technologic Branch, U. S. Geological Survey, has associated himself with ARTHUR D. LITTLE, Laboratory of Engineering Chemistry of Boston, in charge of the department of fuel engineering. Mr. Randall was formerly connected with R. W. Hunt & Co. and Westinghouse, Church, Kerr & Co., and later in charge of the steam engineering laboratory of the University of Illinois and of steam and boiler tests at the St. Louis exposition.

EDITORIAL.

THE THERMOMETER promises to pass the tariff bill immediately.

PREDICTION of higher rates on call loans has been justified already. Money is moving more freely into industrial development, and interest is rising rapidly.

TRAVEL to Alaska is heavy now. The *Corwin* reached Nome May 28, maintaining her record of being first to arrive. The steamers sailing the last of this week are crowded, many having stayed over to see the opening of the Exposition at Seattle, in which Alaskans have large interest.

FROM CANADA comes a new nomenclature. Time-honored custom had recognized a division of metals into 'noble' and 'base' or 'precious' and 'common'. The terms 'superior' and 'inferior', as now used in Ontario law, have something to commend them.

MATERIAL for a new romance is being gathered in the Montreal River district of Ontario by Mr. Julian Hawthorne. These romantic operations are being conducted systematically by the syndicate method. The first novel issued was the Temagami-Cobalt Mines; others in press are the Elk Lake Mines, and the Montreal James, Limited. There is also material available for a farce, which will undoubtedly be later exploited.

LABOR UNIONS have often shown disregard for economic principles. The United Mine Workers of America, however, have decided to accept Asiatics into full membership, and have sent organizers into Western Canada to bring the Japanese into line. This is done frankly on the basis of necessity. If the Japanese are not admitted the organization can not expect to control the labor situation in the coal mines of British Columbia and Alberta, any more than it could have in the East and South without admitting 'hunkies' and negroes. Thus economic principles triumph over race prejudice.

COLUMBIA UNIVERSITY has, this week, conferred honorary degrees upon two well known men connected with the mining industry. Mr. Benjamin B. Lawrence is an alumnus of the School of Mines and was recently elected a trustee of the University which has now conferred upon him the degree of Master of Science. His friends in Colorado, and elsewhere, will be glad that this member of the mining profession has been thus distinguished by his alma mater. Mr. S. F. Emmons was made a Doctor of Science, and thereby Columbia University honors a graduate of Harvard whose whole career exemplifies a devotion to science as consistent as it

has been useful. No man living has done greater service in the application of geology to mining, and it is not too much to say that throughout the West the news of the latest honor done to the expositor of Leadville will be received with keen pleasure.

PERMITTED explosives only are used abroad in coal mines, and to obtain a permit an explosive must meet certain government tests. A similar system is about to be adopted here by co-operation of the powder-makers and the Government. Some thirty powders, manufactured for use in coal mining were sometime since submitted for trial at the Geological Survey testing plant at Pittsburg. These included samples from both the 'Trust' and 'Independent' makers, and the tests were agreed on in advance. Each sample required about one hundred and forty individual tests, besides numerous analyses. It now develops that only seventeen of the thirty explosives tried, stood the test. This demonstrates, if anything, the need and the usefulness of some such system of testing and marking powders. Not long ago a powder which had been issued to miners in a certain coal mine, was tested and found to contain less than six per cent of grains of the size marked on the package. As size largely controls the speed of burning, we have in this misbranding a sufficient cause for many accidents. In determining the proper character of powders for mine use, and in certifying to the quality of those on the market, the Technological Branch of the Geological Survey is doing part of the work which would be expected of a Bureau of Mines. We are particularly glad to see this done with the co-operation of the manufacturers.

EARTHQUAKES are confined to no particular part of the country, as is witnessed by the shock felt at Chicago May 27. This five-second quake did no particular damage, but reminded the inhabitants of Iowa, Wisconsin, Michigan, Missouri, and Illinois of the power of subterranean forces. The last preceding shock of any importance in this region occurred October 31, 1895. The greatest earthquake the Mississippi Valley is known to have suffered was in 1811. Earth tremblings occurred at intervals for two years, and would have been exceedingly destructive if the country had then been densely settled. As it was, the Mississippi was temporarily reversed and many important physiographic changes occurred. Among the lakes then formed was Reelfoot, in Tennessee, recently made famous by White Cap outrages in its vicinity, and by the notable and refreshing manner in which the majesty of the law was vindicated by an able executive. Other lakes and topographic marks show that this, the New Madrid earthquake, was one of the most notable in historic times, all of which is substantiated by contemporary accounts. The shock of last week was not important. A few chimneys were toppled over, a few small fires were started, a quiescent artesian well in Lincoln Park was set spouting, and the inhabitants of our second city were given a new sensation—something hard to give a Chicago man. We note that Chicago is duly grateful, and regards the incident with half-pleased interest. Earthquakes are

among the risks of life. They can not be prevented, and can only be dimly foretold, but they may be met with that cheerful courage which is after all one of our greatest national assets.

Valuation of Coal Land.

Valuation of coal land is not easy; not because it is difficult to estimate the amount of coal in the ground, nor even because of difficulties in fixing the probable selling price. Both can be determined more easily and usually more accurately than in the case of mines of other minerals. The unknown element is the interest-charge accruing before the coal is sold. Where there is a surplus of coal-land it is clear that only a portion of the coal can be marketed at any one time, and in the case of large holdings it is years before all can be sold. Against the future selling price must be offset the accumulated interest-charge on the present purchase-price. Practically, coal-land in the United States, while affording one of the safest investments for people having no desire for prompt returns on their money, is of no immediate value except to the relatively limited extent required to satisfy present market requirements. This has been proved by repeated failure of attempts to make the output of a few mines carry the interest-charge on large holdings. Land is valuable for the coal that is in it only in proportion to the market the owner is able to command.

Such considerations, among others, were doubtless influential in determining the early policy of the Land Office in the matter of sale of coal-lands. These were regularly sold at the minimum price—the nominal sums of \$10 and \$20 per acre. Even at this they were the highest priced Government lands. In general the attitude of the Government was that the increment of value resulting from the settlement of the western country should go to the people who put their money into the West. While this resulted frequently in the enrichment of speculators, it also, in a large way, helped the West and therefore helped the country as a whole.

Prices of the coal-lands of the public domain are now being raised. As pointed out in our Washington correspondence last week, the lands in a particular township in Wyoming that formerly would have been valued at \$460,000 are now held at \$2,800,000. Such an increase in valuation, even though it still amounts to only 12 per cent of the value of the land on a present royalty basis, can produce but one result—the lands will only be sold as they are actually needed for mining purposes. This should reduce the danger of monopoly, without promoting over-production and wasteful competition. In the end it should give future generations cheaper coal. The unearned increment will go in part to the nation rather than to individuals. All this is good, but to complete the plan the law should be changed so that individuals and companies may honestly acquire holdings of the size demanded by modern operations. This was recommended by Mr. R. A. Ballinger when Commissioner of the Land Office, and now that he is Secretary of the Interior it will doubtless be further urged. Another point which seems to us equally im-

portant is that provision be made for a special portion of the increment to go to the State or county in which the land is situated. The increase in value comes from the growth in the country at large, it is true, but in a special way the actual settlers deserve a share in whatever augmentation comes from the development of their immediate district.

Nickel, a Canadian Monopoly.

Toronto despatches announce that the Ontario legislature is cogitating a renewed attack upon the nickel industry. We fully sympathize with the desire to benefit the Province by refining the Sudbury matte at home, but prohibition of exportation of any commodity is a limitation of the market, and amounts to coercion. The consumption of nickel in naval construction is the basis of the industry. England needs nickel for her Dreadnaughts, and might have used a great deal more than she has but for Mr. Asquith's somnolence. Germany has been buying plenty of nickel in the open market, as Mr. Asquith should have done. The Kaiser stole a march on the British in laying down warships so fast that the only way to catch up with her naval program would in truth be to hamper her in obtaining necessary supplies. That Ontario has furnished munitions of war to the menacing Teuton is now being made a patriotic pretext for squeezing the Sudbury miners. The appeal to loyalty is sure of lusty applause; when it was a question of making business for more Canadians it was open to discussion; economic problems are instruments for jugglers on both sides of the midway, and the public generally passes on in a state of bewilderment; but there is no argument required when appeal is made for defense of the flag; the only thing possible is to wash down grim determination in copious drafts of MacLaren's 'malt', and shut off the dreadful German from buying nickel, with shouts of "God save the King." This would be well enough were it actually possible to injure the belligerent foreigner by such restrictions, but there are other deposits in the world than those of Sudbury, and nothing will cause their development more speedily than to withhold Canadian competition. The reason for the present monopoly of the Ontario nickel producers is purely commercial, which is a fact apparently overlooked by the Ontario politicians. Another point which has evidently been overlooked consists in the delicate position in which Great Britain and Canada would find themselves should Germany choose to retaliate by prohibiting the export of potash. The peril from a suppression of this trade is such that the late Edward Atkinson and a group of philanthropic gentlemen in Boston subscribed capital for a potash-hunt, from purely patriotic motives. The search ended in failure, and the fact is that Germany produces all of that vitally necessary substance which is used in Great Britain, in Canada, and in the United States today, and there is no other source for a sufficient supply. We have no quarrel with Ontario in her desire to compel the refining of nickel within her borders. That is a matter of business, and if the effort should demonstrate that it only stimulated rivals, Ontario would promptly recede from her posi-

tion. But to prohibit exportation on the plea of protecting the Mother Country would be in effect an expropriation of the property of men who were invited by liberal laws to invest capital which has enriched the Dominion and at the same time, properly enough, the men who developed the nickel industry. It would limit them to a restricted market, and the Admiralty could elect what price the producers should receive. The Ontario Government has committed numerous follies in its administration of mineral resources; restriction of the nickel industry would be the crowning absurdity.

Mining Claims on Private Land Grants.

In the first session of the last Congress a bill was introduced into the House by Delegate William H. Andrews of New Mexico, permitting the location, according to the Federal mining laws, of claims to gold, silver, and quicksilver deposits on grants confirmed by the Court of Private Land Claims. The purport of this bill has excited interest and speculation. Many have thought it masked a blow at the Railroad land grants, and others have averred that it threatened lands held under title flowing from early Spanish and Mexican concessions, wherever situated. The bill is, in fact, only one of a crop of recurrent efforts at legislation which spring up at each Congressional session. It has nothing to do with the railroad lands. Those are covered by title issued under authority of Acts of Congress, and carry absolute possession. Whatever may have been the intention of Congress when conceding those princely subventions, the issuance of patent carries with it a final determination of the character of the land. Furthermore, a large number of the old Mexican grants has been placed beyond the reach of further legislation. The California grants have been confirmed under Congressional enactment which created a special Board of Land Commissioners for that purpose, whose action was subsequently passed upon by the Federal Courts, and patents issued thereon without reservation. In construing these patents Mr. Justice Stephen J. Field, speaking for the Supreme Court of California in the so-called Mariposa case (*Fremont v. Flower*, 17 Cal. 199, 79 Am. Dec. 123), affirmed the principle that patents issued under such circumstances carried the minerals.

This decision was in accordance with the Common Law of England, adopted as fundamental in this country. The Mexican grants were not patents, and on the cession of territory to the United States the title necessarily passed to the Government, which was bound to respect the rights of those who held grants under authority of Mexico. These were subject to the limitations of the Roman law, which establishes the right to mines as inalienable from the sovereign power unless specifically conveyed. Yet it was held in California that patents issued by the United States confirming ownership in such lands were not limited by the principles of the Roman law, since the passing of title required that it should be in accord with the principles governing these matters under our own legal system.

The question was, however, re-opened by the case

of the United States *v.* San Pedro & Canyon del Agua Co. (4 N. M. 225, 17 Pac. 337), where the right to minerals was ultimately denied by the United States Supreme Court (146 U. S. 120, 13 Sup. Ct. Rep. 94), unless specifically conceded by the terms of the grant. The validity of right to mines on such a grant was not decided, but the inference was unavoidable that tenure was at least open to question.

In 1891 an Act of Congress was passed creating a Court of Private Land Claims having jurisdiction over Mexican grants in Colorado, Wyoming, Utah, Nevada, New Mexico, and Arizona. This act introduced a consideration of title at variance with the decision previously reached in regard to the grants in California. It stated, in part:

"No allowance or confirmation of any claim shall confer any right or title to any gold or silver or quicksilver mines or minerals of the same, unless the grant claimed effected the donation or sale of such mines or minerals to the grantee, or unless the grantee has become otherwise entitled thereto in law or equity; but all such mines and minerals shall remain the property of the United States, with the right of working the same, which fact shall be stated in all patents issued under this act. But no such mines shall be worked on any property confirmed by this act without the consent of the owner of such property, until specially authorized thereto by an act of Congress hereafter passed."

Thus it appears that the bill presented by Mr. Andrews is only one of the annual answers to the call for further legislation sounded in the closing sentence of the section above quoted. The statute now on the books does not throw open adjudicated grants to prospectors, even where the Court has found that mineral rights were not conceded originally. The right to prospect and to locate mineral claims exists only on public lands. Such adjudicated grants are not public lands, and hence special legislation is required to permit the utilization of mineral deposits on such areas. The bill presented by Mr. Andrews purports to cut the Gordian knot, but the situation is full of difficulties and perplexities. It is still required to determine the fact of conveyance or reservation of the mineral rights by the original title where the grants have not been adjudicated, and regard is due to rights acquired by the owner in law or equity. Thus the tenure of the new locator is subject to court decree, as under the statute of 1891. In the case of the Maxwell grant, the owners have made private regulations under which prospectors may search for minerals and acquire rights, subject to certain regulations which are definite. This is a sensible procedure, and the plan might be advantageously adopted by owners of grants where the titles have not yet been passed upon. Concessions under royalty, applicable without invidious distinction to all comers, would be better than the present doubtful status under the law. Custom is as good as law, and in the case of hard problems such as this, where the conflicting interests are so strong as to keep the controversy from legislative determination, the development of an equitable and honorable usage is more desirable than controversy.

BY THE WAY.

Following is a portion of the address recently made by Rudyard Kipling before the students of McGill University, Montreal:

When, to use a detestable phrase, you go out into the battle of life you will be confronted by an organized conspiracy which will try to make you believe that the world is governed by the idea of wealth for wealth's sake, and that all means which lead to the requisition of that wealth are at least expedient.

Now, I do not ask you not to be carried away by the first rush of the great game of life. That is expecting you to be more than human. But I do ask, after the first heat of the game, that you draw breath and watch your fellows for awhile. Sooner or later you will see some man to whom the idea of wealth as mere wealth does not appeal, whom the methods of amassing that wealth do not interest, and who will not accept money if you offer it to him at a certain price.

I would like you to study that man. I would like you better to be that man, because from the lower point of view it doesn't pay to be obsessed by the desire of wealth for wealth's sake. If more wealth is necessary to you, for purposes not your own, use your left hand to acquire it, but keep your right hand for your proper work in life. If you employ both arms in that game you will be in danger of stooping; in danger also of losing your soul. But in spite of everything you may succeed, you may be successful, you may acquire enormous wealth, in which case I warn you that you stand in grave danger of being spoken and written of and pointed out as a smart man. And that is one of the most terrible calamities that can overtake a sane, civilized white man in our empire today.

They say youth is the season of hope, ambition, and uplift—that the last word youth needs is an exhortation to be cheerful. Some of you here know, and I remember, that youth can be a season of great depression, despondencies, doubts, and waverings, the worse because they seem to be peculiar to ourselves and incommunicable to our fellows.

I know of what I speak. This is due to a variety of causes, the chief of which is the egotism of the human animal itself. But I can tell you for your comfort that the chief cure for it is to interest yourself, to lose yourself, in some issue not personal to yourself—in another man's trouble or, preferably, another man's joy. But if the dark hour does not vanish, as sometimes it doesn't; if the black will not lift, as sometimes it will not; let me tell you again for your comfort that there are many liars in the world, but there are no liars like our own sensations. The despair and the horror mean nothing, because there is for you nothing irremediable, nothing ineffaceable, nothing irrecoverable in anything you may have said or thought or done. If for any reason you cannot believe or have not been taught to believe in the infinite mercy of Heaven, which has made us all, and will take care we do not go far astray, at least believe that you are not yet sufficiently important to be taken too seriously by the powers above us or beneath us.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. H. MACKENZIE is at New York.

REGIS CHAUVENET is at Ely, Nevada.

THOMAS G. LOCKHART has been in Denver.

ARTHUR SHUTTS has gone to Nome, Alaska.

A. D. HODGES, Jr., has been in San Francisco.

W. H. SIRDEVAN has just left for Nome, Alaska.

EDWARD L. DUFOURCQ has been in San Francisco.

JOHN C. BRENNON, of Mexico City, is in New York.

WHITMAN SYMMES was in San Francisco this week.

DOUGLAS WATERMAN has gone to La Union, Salvador.

W. C. WYNKOOP has returned from Plumas county, California.

STEPHEN BIRCH is on his way to the Copper River district, Alaska.

J. A. BARR is examining mines in the Golconda district, Montana.

HENRY BRATNOBER expects to go to Nome, Alaska, at an early date.

H. C. BEELER has gone to Hailey, Idaho, to reconstruct the Croesus mill.

H. L. THOMPSON was in San Francisco, on his way to Seattle.

C. O. MOSS is manager for the Kansas City-Goldfield Mining Company.

ELWYN W. STEBBINS has returned to San Francisco from Oaxaca, Mexico.

WM. M. BREWER, who has been in the hospital at Vancouver, is convalescent.

FREDERIC LYON, assistant manager for the U. S. S., R. & M. Co., is in San Francisco.

A. H. ELFTMAN has been in San Francisco, on his way to Nevada City, California.

PERCY E. BARBOUR has returned from Alamos, Mexico, and is now in San Francisco.

VICTOR E. KERR is manager for the Gold King Con. Mines, near Gladstone, Colorado.

GEORGE D. STONESTREET is at Salt Lake, but expects to return to New York shortly.

WM. H. RADFORD has gone to examine the platinum placers of the Condoto river, Colombia.

THOS. T. READ, of Tientsin, will visit mines in Japan, Korea, and East Siberia this summer.

VICTOR RAKOWSKY has gone to the Cascade mountains, and from there will go to Butte, Montana.

J. O. CAMPBELL has been appointed receiver for the Gold Prince mine, at Animas Forks, Colorado.

J. J. SPEAK, of Hooper & Speak, has left London for West Africa, where the firm has mining interests.

WALTER W. BRADLEY has accepted a position with the De Lamar Mining Co., Ltd., at De Lamar, Idaho.

E. W. BROOKS, of Los Angeles, will sail from Seattle shortly for Alaska, to examine copper properties.

M. R. CAMPBELL and E. W. PARKER, of the U. S. Geological Survey, are examining the Stone Canyon coalfield.

A. E. DRUCKER is at the Waihi mine, in New Zealand, having just visited West Australia and New South Wales.

H. C. CUTLER, managing engineer for Nixon & Wingfield, resigned on the dissolution of that partnership, and has resumed general practice at Goldfield.

E. W. DUFFEE has resigned as general superintendent for the Daly Judge Mining Co., to accept the position of general manager for the Alvarado Gold Mining Co., Congress Junction, Arizona. He will make his home in Los Angeles.

THE SCHOOL OF MINES of South Dakota celebrated its twenty-second annual commencement June 2.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Copper Queen smelter at Douglas has blown in two new blast-furnaces with a daily capacity of 500 tons each. This makes a total of ten furnaces in this plant, to handle the ores of the Warren district and the concentrate of the Moctezuma Copper Co. of Nacozari.—The Calumet & Arizona is working at three points. Ore is being hoisted through the Oliver and Mag shafts, while at the Powell the work is purely development. The first station will be cut in the Powell shaft at the 600-ft. level, and from this point cross-cutting toward the Shattuck property and in the opposite direction will begin.—The Superior & Pittsburg's working shafts are now the Cole, Junction, and Hoatson. All are producing ore sufficient for a monthly copper output of 2,300,000 lb.—From the No. 3 shaft, the property of the original Lake Superior & Pittsburg Co., in the vicinity of Don Luis, considerable good ore is now being taken from the surface workings. This old shaft is connected with the 100-ft. level of the Cole shaft.—The Shattuck continues its work of developing the orebody on the 600-ft. level. Its extent is yet unknown, but it has been cut for more than 200 ft.—At the Denn exploration work continues on the 1250-ft. level. A cross-cut is now being run in the direction of the Junction which will soon reach the point corresponding with the location of ore encountered at the 1000 and 1100-ft. levels in this property.—A vein carrying copper, lead, and silver has been cut on the Doran & Gallagher property at Paradise.

MOHAVE COUNTY.

A force of miners has been sent out from Kingman to the Hackberry mines, as work on that property has been resumed.—J. A. Hamme is sinking on his mines in the Walnut Creek district, having the shaft down 75 ft.—E. J. McNulty, superintendent of the Aztec Turquoise Mining Co. at Mineral Park reports that there is enough turquoise in sight and around the Park to supply the demand for years. The mineral occurs in irregular streaks throughout the great mass of porphyry which forms the southern entrance to the basin.—F. B. F. Rhodes, representing the United States Zinc Co. of Pueblo, Colorado, went out to the Golconda mine in company with the general manager, John Boyle, Jr. Mr. Rhodes is purchasing low-grade mine products for his plant, which is intended to treat ores that can not be handled in the smelters.—The three-compartment shaft on the Enterprise mine, in the Wallapai mountains, is being sunk from the 200-ft. to the 400-ft. level. At this point a cross-cut will be run to the vein, which was 25 ft. wide at the 200. W. J. Martin is superintendent.

PIMA COUNTY.

Ore shipments from the Twin Buttes mine to the El Paso smelter amount to 400 tons per week. William McDermott is superintendent.

PINAL COUNTY.

F. S. Hoyt, manager for the Superstition Mountain Mining Co., has purchased a large concentrating plant that was installed in the Cave Creek district but never used, and will move it to the company's mines, situated in the Superstition mountains, about 45 miles north of Florence, as soon as the wagon road now in course of construction from Hewett station to the mines is completed.

YUMA COUNTY.

Barney Quinn, of Winchester, sold the Sitting Bull mine to J. D. Mitchell, of Salt Lake, and A. Mathews, of Marquette, who are representing Eastern capitalists.—Arthur G. Munn's claims near the Colorado river between Needles and Parker have been acquired by the California Nitrate Company.

Shaft No. 1 of the Hillside Mining Co., at Salome, is now down about 25 ft. The vein on the surface was only 15 in. wide, but has now increased to 5 ft., a sample of which averaged \$8 per ton. About 600 ft. from this shaft the com-

pany has begun driving an adit to cross three veins that are exposed on the surface.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence).—The miners' strike has been settled on terms satisfactory to the operators, and practically all the properties are again working full-handed.—The main shaft at the Bunker Hill has attained a depth of 2200 ft., and drifts are being extended from the 1750 and 1950-ft. stations to strike the vein. This property has paid dividends steadily for four years. Twenty stamps are dropping and 20 more will be installed. E. H. Harrington is superintendent.—At the South Eureka extensive operations are going on from the 2300 to the 2750-ft. levels. About 6000 tons of fair-grade ore is handled per month. Half of this is treated at the 20-stamp mill on the ground, the rest at the Central Eureka mill. B. C. Clark is manager.—At the Fremont Consolidated ore is being mined to the 1500-ft. level and treated in the 40-stamp mill.—Arrangements are being made at the Original Amador for the erection of a 20-stamp mill. A large reserve of milling ore has been opened in the mine.—Operations at the Key-stone are progressing steadily. The property is equipped with a 60-stamp mill, a large electric compressor, and steam hoist.—About 150 men are working at the Kennedy. The work of sinking the 3500-ft. shaft deeper is progressing steadily. The mill is running at full capacity.

Jackson, May 29.

INYO COUNTY.

(Special Correspondence).—At the Cerro Gordo extensive developments are going on around the 1000-ft. level, and steady shipments of ore are being maintained to the Keeler smelter. The company is busily arranging for the projected enlargement of the Keeler plant, and it is thought that active work will shortly commence.—The unwatering of the Tower mine is progressing.—Information from Greenwater indicates that the orebody recently opened at the Greenwater-Death Valley mine is too low-grade for commercial purposes. The ore was cut on the 1000-ft. level and the shaft will be sent down 500 ft. deeper, in the hope of the grade improving with depth. If this fails it is reported that an effort will be made to secure properties elsewhere in order to reimburse the stockholders. With the exception of the Greenwater-Death Valley, no properties are now working at Greenwater. The district has been practically abandoned, the gold as well as copper propositions failing to come up to expectations.

Bishop, May 29.

NEVADA COUNTY.

The Fairview mine, near Washington, opened a \$7000 pocket in a raise. The mine is being opened through an adit that was driven 900 ft. to cut the vein. Drifts were run along the vein 160 ft. and a raise started to the surface for an air shaft. When up 200 ft. this broke into the pocket. The ore carries considerable manganese and averages about \$17 per ton gold.—At the Red Ledge mine, two miles south of Washington a bunch of rich ore was found in a cut just below the tunnel. The pocket was uncovered at a depth of 3 ft. An adit will be started lower to give a depth of 150 ft. on the vein. The mine is owned by Foster Williamson and Clyde Cole. It is composed of five claims, and a surface sampling of the vein has shown more than \$2 of free-milling gold.—L. W. Williams and associates have been prospecting a small vein of galena ore in the vicinity of the Mason ranch, about 12 miles from Grass Valley. A shaft is down 24 ft., from which a cross-cut has been driven 18 ft. Samples of ore taken from these workings gave an average assay value of 6% lead and \$3.50 per ton in gold.—At the Montana mine, in the Nevada City district, a number of improvements have recently been completed. A new shaft-house has been erected, a hoist of sufficient capacity to sink to a depth of 1000 ft., and a Sullivan air-compressor of 3-drill capacity installed. A Pelton wheel furnishes the power. During the past month some good ore has been cut, and the manager, W. G. Drown, reports the outlook bright, and the results recently obtained has fully

justified the work done, and the work of prospecting and developing the mine will continue with a force of 14 men.—The shaft at the Pittsburg has been unwatered to the 300-ft. level. The mill is being overhauled. Mark B. Kerr is superintendent.—The Hill mine has been closed down and the pumps taken out by the lessees. The vein encountered near the surface failed to persist with depth.—Two new plunger pumps are being installed at the Empire, and soon after they have been placed in commission the work of sinking the shaft will commence; the 40-stamp mill is running constantly on good ore.—Active development continues below the 4500-ft. level at the North Star mines. The 6-ft. main vein is showing up well and 80 stamps are dropping.—Operations have been resumed at the Kenosha and the shaft is going down steadily. George W. Root is manager.

SIERRA COUNTY.

Three claims at Alleghany owned by Wm. Ireland, Jr., have been bonded by C. C. Ward. The claims are on Kanaka creek, and are all patented.—The Cleveland mine, near Sierra City, has been bonded by Charles Brown of Forest.—The Omega gravel mill, near Forest, is to be started the early part of this month. Considerable outside work is being done, and in the mine the gravel is broken ready for the mill.—The dumps and flumes are being put in repair at the White Bear mine; gravel chutes put in underground and preparations made to wash the gravel recently uncovered.—Work has been started on the Blue Jay group of claims by W. A. Lotspeich, who has a bond on them. The claims are on the serpentine contact west of the old City of Six gravel diggings in the head of Slug canyon.—Good ore has been found in the old Kate Hardy mine, near Forest. The ore carries considerable galena. Tyler Dudley is in charge of the work.—A 2-ft. vein was cut by the cross-cut from the bottom of the shaft at the Bixby mine.—W. F. Corbett, of Lake county, has bonded the San Fernando quartz mine, on St. Charles hill.—H. L. Johnson and L. P. Woodbury, who have the Rainbow mine, at Alleghany, under lease, have cut a shoot of high-grade ore which assays \$60 per lb. The find was made 400 ft. below the old workings.

TRINITY COUNTY.

The Trinity River Mining Co. has let the contract for hauling 120,000 lb. of freight from Redding to its mine, two miles above Lewiston, to Frank Dalton. The company recently completed a long tunnel, through which the Trinity river is to be diverted while the river-bed is worked for its placer gold.—A 28-in. vein was cut by a raise in the Oriole mine. John Shuford is superintendent.

COLORADO.

CHATEAU COUNTY.

The Mary Murphy mine on Chalk creek has been purchased by an English syndicate. A 100-stamp mill will be erected by Harold F. Carpenter, who is the company's representative at the mine.

CLEAR CREEK COUNTY.

(Special Correspondence).—Work will be resumed some time next week in the advance of the Vidler tunnel in East Argentine. The transmission line for the delivery of electric power has been completed. This tunnel is to be driven during the summer and fall months from both ends, and it is hoped that connection will be made before the cold weather arrives. About 2200 ft. of ground remain to be broken. The bore will be equipped with a trolley system, but is designed primarily for railroad purposes. The property is now owned and operated by the Argentine-Montezuma M. M. T. & T. Co., financed by English capitalists.—The Donaldson and Centurion mines, embracing an area of 400 acres of mineral-bearing ground on Donaldson Mtn., have been consolidated. A working fund of \$250,000 has been subscribed by English and New York capitalists and a big force of men will be employed. The corporation will be known in the future as the Donaldson Mines Co. It has also secured the Carpenter smelter at Golden. The capacity at the present time is 500 tons per day, but another unit may be added. It is reported that a lead furnace will be

installed. H. A. Reidel, of Denver, is general manager for the new company.—It is expected that during the next week the raise being put through from the west drift of the Phillips vein will make connection with the Seven-Thirty shaft workings. J. H. Robeson, manager, stated that it would be necessary to cross-cut 30 ft. to reach the shaft. Already 25 ft. of ground has been broken. Great care is being exercised, as the shaft workings embrace seven miles of levels and drifts which are nearly all filled with water.—The new adit started at the Josephine mine on McClellan Mtn., cut a streak of lead ore from 6 to 10 in. wide, assaying from \$60 to \$65 per ton in silver and lead. This adit was started about 250 ft. farther up the hill from the lower workings for the purpose of proving the continuity of the ore-shoots.—A vein of ore 13 ft. wide has been cut in the adit being driven on the Centennial, on Leavenworth Mtn. Samples assay from \$15 to \$20 per ton in gold, silver, and copper. It is reported that some time during the present year this property will be equipped with a stamp-mill. Water for the operation of the machinery will be pumped from the shaft workings of the mine. David Kennedy is manager.—Byers & Co., leasing on the Everett and Lebanon mines, Republican Mtn., have encountered a 16-in. streak of wire silver that mills from \$115 to \$125 per ton in silver and lead. A raise is being carried from the Everett level to connect with the Lebanon workings, about 200 ft. above.—On the Pay Rock Extension vein, a streak of \$90 silver-lead ore from 6 to 8 in. wide is being followed.—Another lode was cut in the Prudential adit this week. Only scattered ore is showing. F. A. Maxwell is manager.—Ericson & Co., leasing on the Seven-Thirty, had a shipment of 11 tons of ore last week that was settled for on the basis of 625 oz. silver per ton, and 18% lead. They are stoping on a streak of ore that is from 12 to 18 in. wide, the ground having been opened for 90 ft.—Bowen & Co., leasing on the Frostberg, are sending out regular shipments of both first and second-class ore. The lead-zinc is being sent to the Mendota mill. The smelting product is sold at the Georgetown sampler. The first-class returns from \$76 to \$80 per ton. Glasson & Co., leasing on the same property, are stoping smelting ore from 16 to 20 in. wide, assaying 150 oz. silver per ton.—At the Smuggler mine, on Brown Mtn., in addition to lessees, a good force of men is being employed on company account. B. C. Catren, Jr., is resident agent.

Georgetown, May 28.

GILPIN COUNTY.

The Great Bonanza Gold Mining Co. is continuing development work on its Next President mine, on Bobtail hill. Two winzes have been sunk from the 460-ft. level in a vein that is from 3 to 5 ft. wide. The ore assays about \$8 per ton. Cecil C. Morgan is manager.—Cross-cutting is being carried on in the west side at a depth of 700 ft. in the Buell mine, in Gregory district, to cut the veins of the Buell group. Herman Lundberg is in charge of the development. A raise is also being cut through from the 600 to the 500-ft. level, on the east side of the shaft. The Buell mill is keeping 45 stamps dropping steadily on Buell and custom ores, it being necessary at times to run the mill all night to handle the increasing supply. Charles Cox is foreman.—The Leavenworth mine, in Leavenworth gulch, has been started up by Clinton Reed and associates of Denver. Work is being carried on at a depth of 200 ft., where they are driving on the vein for the junction with the Calhoun vein. Two classes of smelting ore are being shipped, to thoroughly test its value. Wm. C. Le Prowse is in charge of the work.—A pool of Austrian lessees have started up the San Juan mine, on Quartz hill. They are shipping over the lines of the Gilpin Tramway company to Black Hawk mills for treatment.—Alfred Anderson has started up the Casto mine, on Winnebago hill, and is keeping up some development work in the lower levels. There is a first-class plant on the property.

LAKE COUNTY.

Lessees of the Chrysolite property on Fryer hill are making regular shipments. The ore is chiefly iron, but occasional rich streaks of silver are cut. Peter McCre

vey is the manager of the property.—Work has been started on the towers for the aerial tramway that is to convey the ore from the Tucson mine to the Denver & Rio Grande railroad.—The Coon Valley mine on Rock hill has entered the contact between the porphyry and lime at a depth of 800 ft. and drifting along this contact has now been started. Frank Feehan is superintendent.—Twenty-five tons of lead ore is being shipped daily from the Gnu shaft on the Nisi Prius property, which John Harvey has under lease.—The Langola Mining Co. has started operations on the Pyrnees property on upper Carbonate hill. A new pumping plant has been installed which is expected to drain the mine in several weeks. A. E. Hanifen is manager.—The Cleveland shaft of the New Monarch Mining Co. on Little Ellen hill is shipping 120 tons per day. The ore is coming from the fourth, fifth, and sixth levels. A cross-cut has been started from the bottom of the shaft to tap the vein.—The Tenderfoot mine in South Evans gulch is producing 25 tons of ore per day.

SUMMIT COUNTY.

The May clean-up of the four large dredges, two on the Swan and two in French gulch, will approximate \$100,000. All four are operated by electricity.—The O'Reilley property has a 3-ft. vein of sulphide copper and iron ore in the face of their 260-ft. tunnel.—The Country Boy, in French gulch, is producing about 30 tons of zinc-lead ore per day.

TELLER COUNTY.

The Cresson Consolidated Gold Mining & Milling Co. is taking from 80 to 90 tons of ore daily from its properties on Raven and Bull hills. The ore is being mined from the fifth to the ninth level inclusive and averages about \$25 per ton.—Lessees are making regular weekly shipments from the Silver Tip mine to the Golden Cycle mill at Colorado City.—The Blue Bird Leasing Co. is taking out about 1000 tons of ore per month from the Blue Bird mine on Bull hill.—An amalgamating and concentrating plant for the treatment of the tailing dump at the site of the old El Paso Reduction Works, near Gillett, is to be installed by George K. Kimball, of Idaho Springs, who has secured a lease on the dumps. These have been sampled and the average value has been found to approximate \$2.50 per ton, while the cost of treatment by the method proposed will be less than \$1 per ton. An 18 months lease with graded royalties has been secured by J. D. Bryant on the Nil Desperandum and Rhinoceros lode mining claims on the northwestern slope of Raven hill, owned by the Gould Mining Company.

The Iowa Leasing Co., operating the Four Brothers claim of the Agnes Gold Mining Co., has cut a station at a depth of 450 ft. on that Beacon hill property and has commenced driving on the vein exposed near the shaft, in search of an ore-shoot.—A depth of 435 ft. has been reached in the main shaft of the Little Nell gold mine, and sinking will be continued until the 500-ft. point is reached. At this depth a station will be cut and a cross-cut will then be carried to the west side line. At the 300-ft. level a vein of low-grade ore has been exposed.—The W. P. H. mine shipped four cars of milling ore.

IDAHO.

SHOSHONE COUNTY.

Carbonate, ruby silver, and galena ore has been cut in the face of the drift on the Clear Grit Mining Co.'s claims near Delta. They have a depth of 440 ft. on the dip of the vein.—Four feet of galena ore has been cut on the Samson Mining Co.'s property about eight miles west of Murray. The ore, which was encountered in the face of the drift when in 110 ft., assays high in lead and silver.—The Black Horse mine furnished the ore for the first shipment to go all the way by rail from the Murray district to the smelter. The consignment was sent over the Idaho Northern railroad.

Ore was cut in the adit of the Samson Mining & Development Co. when in 111 ft. The assay of this was 65% lead and 116 oz. silver per ton. Four feet of galena ore has been cut on the property of the Samson Mining Co., on Upper Eagle creek, about eight miles west of Murray. A. J. Brainard is manager for the company. The H. E. M.

Mining Co. shipped its first car of ore to the smelter at Tacoma. The ore assays 70% in lead and 30 oz. silver per ton.

KANSAS.

CHEROKEE COUNTY.

A promising ore deposit has been developed west of the business centre of Galena and a 300-ton mill has just been completed by George McCullagh. The plant is in two units, each having a capacity of 150 tons, being built in this fashion because the ore from two leases must be treated separately. Several shafts are down to the orebody and sufficient drifting has been done to ensure good production.—Since the successful drainage of old Short Creek Bottoms there are a large number of sub-lessees at work on this tract. The water is down to the 80-ft. level over most of the land, while at the Murphy mine it is drained to 100 ft. Most of the lessees have opened old shafts and hardly one has failed to find rich ore at shallow levels.—The Lockport Co. has recently acquired the Brinkerhoff land adjoining Short creek bottoms and has installed a centrifugal pump for its immediate unwatering. This will make available for mining purposes 80 acres additional.—A cave-in on a residence lot in the heart of Galena revealed rich ore, and since the removal of the residence a company has leased the lot and has begun mining. A shaft is being sunk through solid ground in order to get to the ore. The mineral is in a loose sand formation and only requires washing to be ready for the market.—The Lizzie D. Mining Co. at Peacock is sinking another shaft on its lease 200 ft. from the former shaft. The new shaft is at the 300-ton mill which will be completed in another month. The ore is found from 173 ft. down.

MISSOURI.

JASPER COUNTY.

Among the recent strikes in this district is an accidental ore find near Lakeside Park by C. T. Bunce while drilling a well. The ore was encountered at 218 ft., continuing to 230 ft. This is the first strike in this vicinity, and as a result there is a great demand for leases on adjoining lands.—One of the best strikes made in the Neck City camp recently occurred on the 1909 lease of the Quick Seven land. The ore was reached at 72 ft. and continued for 15 ft.—Rich 'rosin jack' was struck in the Blendeville camp on the old Colorado tract, from 27 ft. to below the 42-ft. level.—Several drill-holes on the Nowata Mining Co. property are in ore of the sheet formation.—The Little Pitcher Mining Co. at Chitwood has cut a 12-ft. vein after sinking a number of holes in the floor of the drifts.—The Little Hatchet Co. at Duenweg has found a 7-ft. vein of ore at 165 ft.—The ore is being cleaned on hand-jigs.—The Mary Ann Co. is building a mill west of Joplin on a sub-lease of the Morning Hour. Three shafts down to the ore will supply the mill, and a number of dump piles, the accumulation of previous development, will be treated soon.—Two shafts are down 140 ft., with the third down 167 ft.—The new Mandarin, a 400-ton plant, is beginning production near the Chicago-Joplin plant. A shaft is being sunk near the mill to supply the plant.

LAWRENCE COUNTY.

The new Coleman Bros. plant is being rapidly completed, the machinery being now installed. A large dump pile rich in ore is awaiting treatment. The company waited to build the mill until sufficient dirt had been taken from the ground to pay the construction.—Mains & Co., working on the Boston-Aurora ground, cut the ore at 41 ft. The shaft is down 56 ft.—Ore has been cut on the Jones land. The strike was made at the same depth as that made last year by the Federal Zinc Co.—At McDowell, south of Aurora, a new 200-ton plant has been finished for the treatment of the blende ores at the lower levels. At present the mill has a capacity of 100 tons and is used for the silicate ores found at a shallow depth. One shaft is down 165 ft. and the second 220 ft.—Plans are under way for the re-opening of the Springfield mines. During the past week a second run has been found, the zinc being unusually rich. It is said that over \$70,000 worth of zinc-blende has been taken from the Baker tract.

NEWTON COUNTY.

The McKee Mining Co. has just completed a new mill in the Spring City camp and the initial run will soon be made.—Scott & Bankard are installing new machinery on their lease. The company cleaned out the old shaft and found a good run of galena and zinc-blende.—The Silver Plume Mining Co. is to resume operations after a shut-down since last December. This property was developed last year and was the first of the sheet-ground properties in the Granby camp. The shaft is down 229 ft., showing both galena and zinc-blende.

NEVADA.

ESMERALDA COUNTY.

The Lodi smelter, 43 miles northeast of Luning, is to be blown-in during the early part of this month. The initial capacity will be 100 tons per day, drawn largely from the Lodi mine. A small amount of custom ore will be accepted at first, and if the run proves successful the smelter will be enlarged. The Lodi mine has attained a depth of 800 ft. on an ore carrying silver, lead, and gold.

A dividend of 30c. per share was declared by the Goldfield Consolidated. The cost of operations at the new mill is \$2.18.—An improvement has been made in extraction

to the 200-ft. level. At this point a station will be cut and a cross-cut run to the vein.—Five stamps of the Coalition mill have been turned over to lessees to mill the ore from the Wihuja mine. The Wihuja has completed the station at the 425-ft. level and will drive on the vein from that point. The ore assays between \$50 and \$60 per ton.

LINCOLN COUNTY.

(Special Correspondence).—The Quartette mine is showing up splendidly, with large reserves opened in the lower levels and 40 stamps dropping constantly. One hundred men are employed and work is going forward at numerous points.—A vein of low-grade ore which had been driven on for 25 ft., has been cut on the 300-ft. level of the Pittsburg Searchlight. The ore will be stored until fall, when it is planned to erect a new mill.—The shaft at the Philadelphia Searchlight is going down steadily to the 1000-ft. level. The company has expended approximately \$50,000 in the past three months in development work and machinery. The shaft is double-compartment and will cut the vein system at considerable depth.—At the New York Searchlight a cross-cut is being driven to cut the vein. A compressor and drill were recently installed.—Arrangements have been made for the re-opening of the Wharton mine, in

Pioneer, Nevada. Ranger Lease May be Seen on the Left.

at the Combination mill by the installation of a few more concentrators, and by the selection of ore more suited to the limitations of the plant, which was not designed for the purpose of treating sulphide ores.—A drift has been run 200 ft. along the orebody that was cut a short time ago in the workings of the Red Top and Lucky Boy mines. The width of milling ore varies from 15 to 30 ft.—Stations are being cut in the Clermont shaft at the 733, 866, and 1000-ft. levels, preparatory to starting lateral work for reaching the downward projection of known orebodies on the Mohawk and other veins in this portion of the Consolidated territory. Ore-bins of 200 tons capacity are to be constructed at each station, below the levels, and provided with chutes so that the ore can be readily dropped into cars or skips in the shaft.—After idleness of several months, work has been resumed on the Hazel Goldfield lease on the Last Chance claim of the Consolidated property. A much heavier hoisting plant will be installed and drifts, cross-cuts, and raises driven to explore the territory from the 720-ft. level.—A dividend of \$32,000 was declared by the board of directors of the Round Mountain Mining Co. It is expected that the new electrical equipment will be installed by the middle of June, and this will probably increase the capacity of the mill about 25%.—Drifts are being run on the 400 and 500-ft. levels of the Diamondfield Daisy, and ore is being shipped from the 250 and 300-ft. levels. The ore is smelting rather than milling, and when the Goldfield Ely railroad is completed it will be easier to market it than at present. —A cross cut from the shaft on the C. O. D. Consolidated at the 400-ft. level has cut a body of ore that runs from 6 to 20% copper.

HUMBOLDT COUNTY.

The Seven Troughs Trio Mining Co., operating on Mazuma hill, has the mine workings pumped out and the shaft nearly

El Dorado canyon. This property has been idle for several months, although considered a valuable mine. E. M. Martin is superintendent.—The Empire is still tied up by litigation, with little prospect of an early settlement.—An 18-in. shoot of ore running about \$100 per ton has been intersected at the Pompeii mine. The 10-stamp mill is running steadily on Pompeii and custom ore.—The Chief of the Hills lease, on Quartette holdings, has leased the Cyrus Noble mill and is treating all ore running less than \$100 per ton at this plant. Richer ore is shipped to the Needles smelter.—Ten stamps are dropping on good ore at the Duplex.—Searchlight is more active now than at any point of its history. Approximately 1000 men are working and 80 stamps are dropping. The mines are showing improvement with depth and several promising prospects are receiving attention.

Searchlight, May 28.

The shaft on the Alunite claim in the Alunite district is down 340 ft. and that on the Homestake 285 ft.—One hundred tons of manganese ore have been shipped by the Prince Consolidated mine at Pioche to the Tintic smelter. William Lloyd is superintendent.

NYE COUNTY.

Some excellent results are being obtained from the work at Pioneer. The town is situated eight miles north of Rhyolite and is within two miles of the Tonopah & Tidewater tracks.—The Keane Wonder cut a new shoot of ore that ran above the average at the mill. A head-frame has been erected over their new shaft and a hoist is to be installed. Drifts will be started as soon as the hoist is completed.—The Pioneer Leasing Co., working on the Pioneer Bullfrog property, has a 30 ft. breast of ore open. The strike of this vein is approximately north and south, with a 55° dip to the west. Smelter returns from this property

were about \$200,000 for last month.—Two new orebodies have been cut on the Pioneer lease at Rhyolite, about 100 tons of ore is being taken out daily.—The Jefferson mill at Round Mountain is about completed and expected to start soon.—The Rusty Pick Consolidated property has been sold to Eastern capitalists, headed by W. N. Mitchell, of Chicago, and C. W. Hayes, of Goldfield. The Rusty Pick is situated at Ibex and comprises 10 claims. There are about 200 ft. of development work completed upon the ground. One shipment was made at the time that the work was done which was settled for at the rate of \$150 per ton.—The option on the divide group of claims, on Quartzite mountain, has been taken up and the Boston capitalists are now in control of the property. W. H. Spalding has been put in charge.—Milling ore has been cut on the Tripolite property at a depth of 220 feet.

A connection between the 600 and 770-ft. levels of the Tonopah Extension has been completed. The annual report of this company was mailed to its stockholders, and in accordance with the recommendations the directors have decided to erect a 30-stamp mill.

OKLAHOMA.

OTTAWA COUNTY.

One of the deepest and richest strikes in the Miami camp has just been made on the lease of the Miami-Yankee Co. north of the Emma Gordon. The ore occurs below the 200-ft. level, whereas the usual run in this camp is worked from 90 to 105 ft. Two holes have been sunk, finding both galena and zinc-blende.—J. W. Barnes also reports a rich drill-strike in the same vicinity at a depth of 306 ft. Previous drilling showed ore from 187 to 215 ft.—The Turkey Flat Co. is putting up a second-hand plant of 200 tons capacity.—Among other companies erecting mills is the Consolidated, with the material on the ground and the plant started.—The Little Maxine has its mill almost completed.—The Last Chance and Blue Bell have each bought old mills which will be re-modeled.—A good zinc strike was made at Bluejacket recently when a 35-ft. vein of ore was penetrated at a shallow depth.—The first shaft is being sunk in the Fairland camp by Frankenburger and Varner. A considerable amount of prospecting has been done, showing rich beds of lead and zinc in this vicinity.

UTAH.

BEAVER COUNTY.

A shaft has been sunk on the vein of the Moscow Bonanza property by a Salt Lake company holding a lease on that property. The ore averages \$20 gold, 67 oz. silver, and 1½ lead. A shipment will be made soon to the Salt Lake smelter. The company will drive each way on the vein at the 100-ft. level. Dan Ferguson is in charge of the work.—The Red Warrior, in the Star district, is shipping two cars weekly to the smelters. The ore is loaded at Milford.—On the 700-ft. level the Beaver Carbonate has cut an orebody 35 ft. wide. Samples from this orebody recently sent to Salt Lake assayed 10 oz. silver and 10% lead. The company is continuing the raise on the orebody encountered closer to the shaft, and this is looking very good, the ore being a shipping grade. Grant Snyder is manager.

SALT LAKE COUNTY.

The Bingham Mines Co. has secured a contract with the American Smelting & Refining Co. for the smelting of its ores from the Dalton and Lark mines at Lark. This contract will permit the Bingham Mines Co. to maintain steady ore shipments, and it will open the way for a much more extensive campaign of development work at depth in the properties. The company has been shipping in a small way for some time, selling its lead ores on the open market, but this has proved unsatisfactory. Imer Pett is manager.

WASHINGTON.

OKANOGAN COUNTY.

Two drifts are being run on the 150-ft. level at the Olentangy mine.—The Copper World Extension Co. is building a wagon-road along the backbone of Palmer Mtn., to connect with an old road through Golden to Oroville. When completed the company will ship a test carload of ore

If the returns warrant, shipments will be continued.—The Nighthawk Mining Co. is sinking a double-compartment shaft to a depth of 200 ft. Ten stamps are dropping in the mill, and a carload of concentrate will be shipped in a few days.—A contract has been let by the Favorite mine to mine and mill 100 tons of ore to determine the advisability of erecting a mill at that mine.

STEVENS COUNTY.

Work has been started by the United Copper Mines Co., of which Conrad Wolfe, of Spokane, is president on an adit which will give a depth of 1100 ft. below the present workings in the Chewelah district. It is to be 3000 ft. in length and will connect several properties. Mr. Wolfe also reports that 14 ft. of low-grade ore has been encountered on a 350-ft. adit in the Copper Cliff property on Quartzite Mtn.—The Alladin Mining Co. has a large body of galena ore blocked out near Northport, and is installing a concentrator and constructing a large flume to conduct water for power, etc. The company owns a sawmill and has a traction engine for facility in hauling. Peter P. Swanson, of Spokane, is the manager.—Rails and cars have been delivered to the Pittsburg mine on O'Toole Mtn. and work started at the adit level.—A diamond-drill has been installed at the Sunset mine and prospecting will be carried on from the 400-ft. level.—The Bornite Mining Co. has driven an adit 600 ft. and cut about 8 in. of ore. In driving 30 ft. on the vein the ore widened to over 18 in., and assays as high as 19% copper and from 5 to 20 oz. silver per ton. The face of the drift is about 250 ft. from the shaft. It is planned to build a flume from the head of Coyote creek, 1300 ft., to carry water for power sufficient to run all the machinery. Machine-drills are to be installed and preparation made to ship ore. The portal of the adit is so near the bank of the Pend Oreille river that the ore can easily be delivered from the dump to the river barges.—The Metaline Lead Co., of Metaline, has purchased a one-third interest in the Coupon, Mystery, and Dividend claims, in Metaline district.

CANADA.

BRITISH COLUMBIA.

The Placer Gold Mines Co. of Seattle has 55 acres of placer ground on Ruby creek, 17 miles east of Atlin. A flume, pipe-line, and two giants, with the necessary sluices and riffles, constitute the equipment. The placer ground is 50 ft. deep. From the bottom of the shaft drifts have been run on the bedrock which permitted a sampling of that part of the ground. The sampling indicates a value of \$1.66 per yard from the 10-ft. level to bedrock. T. M. Daulton, of Seattle, is general manager of the property and is on the ground directing the work.—The Granby smelter at Grand Forks and that of the Consolidated company at Trail are receiving large shipments from the surrounding districts. The Granby is handling between 25,000 and 30,000 tons per week and the Trail smelter 8000 or 9000 tons weekly.—In the north vein of the Centre Star mine a new orebody has been uncovered which assays about double the usual run of the mine, while the big orebody in the War Eagle, estimated to contain one million dollars in values, is practically untouched.—Phil O'Connor, of the Lardeau, who located a copper property on Queen Charlotte island, has bonded it to the Granby Consolidated for \$100,000.—G. H. Wright, of Vancouver, has taken one year's bond on the Majestic group of claims on Payne mountain, at Sandon, from F. H. Bourne, of Revelstoke, and Charles French, of Vancouver.

ONTARIO.

The Coniagas Reduction Co., Ltd., whose smelter is at Thorold, is to double the capacity of that plant. This addition is to handle the increase of 120 tons per month from the Coniagas mine and 180 tons custom ore.—The Keeley mine, situated about four miles west of Cobalt lake, is installing a new power-plant. It consists of a 150-hp. gas engine to drive a 12-drill compressor and a 35-hp. gas hoisting engine. Boyd Magee has charge of the work.—A 5-drill compressor is being installed at the Wettlaufer mine. The shaft is down 50 ft. and has cut silver ore. A. C. Bailey is superintendent.

Special Correspondence.

LONDON.

Murex Process.—Ekenberg Peat Investigation.

Few facts regarding the Murex magnetic process are yet available. The patents are not yet published, and the inventors naturally do not disclose full details. The process is a wet one. The plant is not dissimilar from that used by Wetherill. The pulp is passed in a thin layer upon a belt, or a Zimmer conveyor underneath, behind which is a magnet. The pulp has been preliminarily mixed with an emulsion of magnetite and oil, and the metallic particles become agglomerated into granules which are sensitive to the action of the magnet. They are taken up by the belt and are carried out of the magnetic field. The unaffected gangue passes over the end of the conveyor or belt and goes to the tailing heap. The amount of emulsion used per ton is comparatively small. The Murex should not be confused with flotation processes. It is, however, possible, that the owners of the Elmore and Minerals Separation processes will argue that the use of oil as a selective agent for the agglomeration of metallic and sulphide particles and to effect adherence thereto of the magnetite, is, to that extent, an infringement. The Murex inventors claim as their great advantage that the process will work with high efficiency on all sorts of ores which are not amenable to other flotation processes. Critics of the process point out that costs will be higher than with other oil concentration processes, inasmuch as the provision of magnetite, and its subsequent removal from the concentrate, have to be considered, in addition to the cost of the electromagnet. Probably employment of the process, when a high commercial extraction can be obtained by the other processes, is not contemplated. In the Murex process it is proposed to effect a separation between the various sulphides in such ores as those of Broken Hill, complex galena and blende mixtures difficult to separate owing to the intimate crystallization, by the admixture of a small quantity of alkaline silicate. The Murex process as applied to Broken Hill ores is to first treat the raw ore in the wet magnetite process, and then use process No. 2 for separating the galena and blende.

From time to time we hear accounts of new methods invented for utilizing peat for fuel. All have failed so far because of the difficulty of removing the water economically. The water which is present in a free form can be removed easily, but the bulk of it is combined with cellulose and cannot be removed by any mechanical means. The application of heat is effective, and the question is one of economy. If the peat be dried by means of hot air or gases the amount of fuel employed is as great as that which is produced by drying the peat. It must be remembered that ordinary peat contains about 85% of water and only 15% of solid matter, so that there is an enormous proportion of water to be evaporated. Drying by the sun in the open air is far too tedious, uncertain, and expensive a process. Dr. Martin Ekenberg, a Swedish engineer, has evolved a new method. In 1903 the Swedish Government recognized the value of his research and placed funds at his disposal. His process is to break up the hydro-cellulose in retorts to which water at temperatures of from 150 to 200° C. is admitted. This heat is sufficient in a very short time to free the water from the combination, so that if on removal from the retort the peat is subjected to pressure, practically the whole of the water can be expelled without difficulty. A briquette is produced which readily burns, and which can also be used for the manufacture of charcoal. At the meeting of the Iron & Steel Institute recently Dr. Ekenberg read a long paper on the subject, giving a history of his experiments. It is claimed that the amount of heat and power used in breaking down the hydro-cellulose by hot water under pressure and subsequently removing all the water in a press, is far less than is required to expel the water by means of dry heat. The process apparently would be somewhat expensive on account of being discontinuous, but it is of great interest where good fuel is scarce.

BRITISH COLUMBIA.

Trail Output. — Granby Shipments. — Coal Strike Settled. — Coke Ovens at Michel. — Sandon. — Gold on Cascade River.

Rossland mining and business men are becoming optimistic again, and in one sense they may well be so. The Consolidated smelter at Trail in April treated 35,490 tons of mixed ore, from which they extracted 410 tons of copper matte and 2264 tons lead bullion, containing gold, \$214,835; silver, \$101,891; copper, \$44,232; and lead, \$146,110; a total metallic production of \$507,068. The refinery turned out 2012 tons of pig lead, worth \$115,927; 2663 oz. gold, \$54,959; and 148,128 oz. silver, value \$75,485; a total of \$246,371. From June 30, 1908 to April 30, this year, the Trail smelter has produced metals to the value of \$4,088,940; of this the refinery must be credited with \$2,096,461. The production of the Le Roi No. 2, Ltd., during April was something over 2200 tons, and the net profits of the company were in the neighborhood of \$35,000. The gross output was \$67,770. A 4-ft. vein of galena has been opened up on the Hattie Brown. The Mayflower has been leased to F. Neal and associates.

The Snowshoe and Granby were the only shippers from the Boundary district during the week ending May 22. The Snowstorm sent out 2120 tons, and the Granby 13,740. The shipments from the Granby mines during the next week or so will be much heavier, as furnaces No. 3 and 4 will be blown in during the coming week. Shipments from the Gold Drop adit will be resumed. It is understood that the Dominion Copper mines, which have been kept unwatered, will be worked again shortly. The amount that is still owing to the miners for wages will be paid immediately. The Argo company has commenced an adit to tap the high-grade veins running through the hill at South Greenwood. On the Golden Zone group, 12 miles from Hedley, the shaft has now attained a depth of 110 ft., and at that depth the vein is over 10 ft. wide and the ore assays \$82.68, \$45.47, and \$20.67 in gold, with a little silver. The lode now worked has been traced on the surface for over 2000 ft. There are two other good lodes on the property, which consist of four claims—the Golden Zone, Irish Boy, B. C., and Silver Bell. All three veins are to be cross-cut at 200 ft. It is estimated that there is already enough ore ready for stoping to supply the 5-stamp mill, and this will shortly be put in operation. Work on the Kingston is giving good results; 12 men are working. A big strike is reported at Twenty Mile creek, on a property being worked by a party of Italians. The vein on the Bruse was cross-cut for 20 ft. on the surface last week, and assays taken returned from 8 to 20% copper.

The strike in the Southern Alberta coalfields, which has been holding back mining and smelting in this district, has been settled, the miners yielding on the open-shop question and the operators in regard to the matter of discrimination as to union men. This will assure a supply of coke for the British Columbia Copper Co. and other plants. The Crows Nest Pass Coal Co. has begun preliminary work on the 1000 coke ovens which will be built at Michel, B. C., during the coming summer.

A lead on the Anthony claim, near Nelson, was uncovered by T. Maher recently. It carries from \$59 to \$117 per ton in gold. This property was known to old-timers as the Robin Hood. The new lead has been exposed 150 ft. and looks very promising. Rumor has it that the Dunsmuir interests will shortly commence work on the Noble Five group at Sandon. This is a rich and promising property, which miners have endeavored in vain to lease during the last few years. There is a good concentrator on the ground which, with a few repairs, will be able to take care of the product of the mine. A strike of gold is reported from Devil's creek, on the Cascade river, near Bankhead, Alberta. Samples of the sand shown at Bankhead appear to carry gold in good quantities.

Leonard Hills, of Chicago, one of a group of capitalists who obtained control of a large area of coal ground on Graham island last fall, has gone East to arrange for the opening and development of the property. W. Evans, Pincher Creek, Alta. with E. Hodgeson, of Vancouver, B. C.,

will have charge of the development work, and arrangements have been made for a production of 150,000 tons of coal in the coming 18 months.

WASHINGTON.

Land Laws. — Bureau of Harbors and Waterways. — Mexican Oil. — California Debris. — Tariff on Antimony. — Patent Laws.

A summary of the important land laws of the United States, written by Knute Nelson, Senator from Minnesota, for publication in the 'Annals of the American Academy of Political and Social Science,' has been made a public document (Senate Document No. 59). It can be obtained through his Senator or Representative by anyone interested. A proof of the article fell into the hands of C. D. Clark, Senator from Wyoming, who called attention to its usefulness and requested that it be printed by the Government. Sylvester C. Smith of Bakersfield, Representative from California, has introduced a bill in the House which provides that the public lands in the State of California, chiefly valuable for mineral oil or asphaltum, may be acquired for these purposes, but that such lands may not be located as placer mining claims. A bill to create a Bureau of Harbors and Waterways under the Department of Commerce and Labor was introduced in the House May 25 by James L. Slayden of San Antonio, Texas, Representative from that State. It was referred to the Committee on Interstate and Foreign Affairs. Mr. Slayden would have the bureau officered by a corps to be known as the Corps of United States Civil Engineers, the chief of the corps to receive a salary of \$10,000 a year. The bureau would consist of the chief, 4 associate chief engineers, 9 department engineers, 50 division engineers, and resident engineers not to exceed 100. Another attempt to give water-power rights to citizens is made in a bill introduced in the House by William A. Oldfield, of Batesville, Ark., Representative from that State. The bill aims to give consent to the erection of a power-house upon lands belonging to the United States on the upper White river, Arkansas. The construction work must not impair the usefulness of any improvement made by the Government for the benefit of navigation. The bill also provides that the withdrawal of water from the river shall at all times be under the direction and control of the Secretary of War, who is authorized to fix, from time to time, reasonable charges for the use of its power.

'The daylight savings act' is a unique bill introduced in the House by Andrew J. Peters, Representative from Boston, Mass. The bill provides that between 2 and 3 o'clock in the morning of each of the first four Sundays in April in each year shall be a small hour, consisting of 40 minutes only, but shall otherwise be reckoned a full hour for all intents and purposes whatsoever in the United States; that the hour between 2 and 3 o'clock in the morning of each of the first four Sundays in each year, except 1909, shall be a long hour, consisting of 80 minutes, but shall otherwise be reckoned as a full hour.

C. D. Chamberlain, of Cleveland, Ohio, representing the independent oil men who are asking for a duty on crude oil, in a statement issued today declares that the investigations of David T. Day of the oil resources of Mexico leave no doubt that the production of Mexico is a menace to the interests involved in competition in the United States. He says that the investigation of Mr. Day has verified the prevailing opinion of the large extent and potentiality of the Mexican field. In a statement some days ago the independent oil men charged that the Standard Oil Co. controlled the Mexican fields, and that it therefore wanted free petroleum. As opposed to this view, Frank Flint, Senator from California, yesterday read to the Senate the following telegram: "Please deny to Congressmen and Senators that the Mexican Petroleum Co. is controlled by the Standard Oil Co. Newspaper reports and reports attributed to David T. Day to this effect have no shadow of foundation. Standard Oil Co. has no connection, direct or indirect, with our interests. Signed, Norman Bridge, Los Angeles, California."

First Lieutenant Charles T. Leeds, Corps of Engineers,

was today nominated by President Taft as a member of the California Debris Commission, in place of Major Charles H. McKinstry, who is to be relieved. The nomination was confirmed by the Senate. Professor Simon Newcomb, the astronomer and mathematician, who has been seriously ill at the Johns Hopkins Hospital, Baltimore, Md., has recovered sufficiently to return to his home at Washington.

On the promise that a new industry would result, the Senate placed a duty on antimony, as regulus or metal, of 1½c. per lb.; on antimony ore, stibnite, and matte containing antimony, 1c. per lb. on the antimony content therein contained. It was shown by J. M. Dixon, Senator from Montana, that under present conditions the United States is importing from \$1,000,000 to \$2,000,000 worth of ore and metal every year, rising from 3,900,000 lb. in 1904 to nearly 9,000,000 lb. in 1907. He declared that nearly all of it is imported, notwithstanding the fact that in 10 or 12 of the Western States antimony ore is found in abundance.

Porter J. McCumber, Senator from North Dakota, has introduced a bill to provide for the utilization of State and Territorial lands in connection with projects under the Reclamation Act. Briefly, the bill provides that if the title to any lands which are acquired for a project under the Reclamation Act be vested in any State or Territory by any act of Congress, other lands of equal acreage in lieu thereof be appropriated and granted, and may be selected by the State or Territory. Robert J. Gamble, Senator from South Dakota, has introduced a bill to authorize the sale of a portion of the surplus and unallotted lands in the Pine Ridge Indian Reservation, in the State of South Dakota. Charles H. Burke, Representative from the same State, has introduced a bill to authorize the sale of the surplus lands in the Rose Bud Indian Reservation.

An amendment proposed to the statutes relating to patents covering inventions which may be of far-reaching importance, has been introduced in the House by John A. Moon of Chattanooga, Representative from Tennessee. The amendment provides that where patents were granted within 17 years and 9 months preceding the date of the passage of this act, the inventor shall have the right to request an extension of his patent beyond the original term of its limitation, under certain conditions. The question of extension of time shall be referred to the Court of Claims. If the patentee can show that without neglect or fault on his part he has failed to obtain from the use and sale of his invention a reasonable remuneration, the patent will be renewed for a period not to exceed 17 years. A plan to erect an electrical power-plant at Portales, New Mexico, for irrigation purposes, has been proposed by William H. Andrews of Albuquerque, New Mexico, Delegate to Congress. Although the Government now has an experiment station at Pittsburg, Pennsylvania, for testing the fuels of the country, C. Bascom Slomp, Representative from Big Stone Gap, Virginia, wants a station in his own district. He has introduced a bill providing for an experiment station at Norton, Virginia.

MEXICO.

Graphite in Sonora. — Zinc Smelting. — Oil Discoveries.

The Santa Maria graphite mines, which are owned by the U. S. Graphite Co., of Saginaw, Mich., are situated about 20 miles south and a little east of La Colorada, in central Sonora. They are the largest amorphous graphite mines on the Western Hemisphere, and probably in the world. The country rock is composed of metamorphosed sandstone, ranging in fineness from shaly material to conglomerate containing pebbles 1½ in. diam. Considerable andalusite in small crystals is developed in the sandstone. The rocks are probably of Upper Triassic (Richmond) age. They are intruded by granite, which has been the metamorphosing agent. Intercalated with the sandstone are at least seven beds of graphite, ranging in thickness up to 24 ft., and standing at high angles. The rocks are considerably folded, and the graphite beds show the effect of movement more than the enclosing sandstone, so that they are in places almost cut off through squeezing, while in other

places they show thickening. The graphite beds are also intruded by granite dikes, and in places the walls are of granite. The graphite was undoubtedly formed through the metamorphism of coal beds, which in other parts of the State are to be found in the form of graphite, coke, anthracite and bituminous coal. The graphite of the Santa Maria deposits is entirely amorphous, and from the main vein worked averages 85 to 86% graphitic carbon. Specimens may be picked which carry 95% graphitic carbon. The company is steadily mining graphite and has accumulated a considerable amount at the mine, as no shipments have been made for some time. However, it expects to begin shipping again shortly. It is working about 30 men in one shift. The graphite is shipped to Saginaw, Mich., for refining. A large part of the best pencils, both of European and American manufacture, are made from this graphite. It is also used for a lubricant, powder coating, and foundry facings. A few miles north of Torres, and three miles west of the railroad, a Pennsylvania company owns graphite deposits, for which a good price was paid a few years ago. A small amount of graphite was shipped, but the property is now lying idle, and it is said that the quality of the bed is not of the best. Prospecting is being carried on for graphite on the east side of the Yaqui river, a few miles above Onavas. The geology is similar to that of the deposits at Santa Maria, about 75 miles west. At San Marcial, between Santa Maria and Onavas, coal is found partly graphitized, and at points on the Yaqui river above Onavas unaltered coal beds are reported, which it is said the Southern Pacific controls and will use for fuel on its Mexican lines.

The attempts being made at Washington to have a duty placed upon zinc ores have given rise to new talk of a zinc smelter in Mexico. Judging by the number of concessions that have been asked of the Mexican Government during the last several months, it would seem probable that something may result. The subject of a zinc smelter in Mexico was gone into most extensively and minutely several years ago by the late A. K. Bohn, who had interested with him J. F. Johnson of Parral. For a time it looked as though the proposition was going to be carried through, but unfortunately Mr. Johnson was at that time engaged with a proposed lead smelter at Jiminez, in connection with the mining interests he was acquiring in the Parral and Almoleva district. He abandoned the zinc smelter to push the lead plant. The latter required more capital than Mr. Johnson was able to command, and the result was that both schemes fell through. That a zinc smelter in Mexico would be a paying proposition is generally believed, and should a tariff be placed on zinc ores entering the United States, it would seem that Mexico would be forced to build zinc smelters. The most natural point for the location of a zinc-smelting plant is at Monterrey, in the State of Nuevo Leon. Here is the centre of a very important district, producing carbonate of zinc of an exceptional quality, and with Mexico's largest coalfields nearby the conditions seem ideal. As a distributing point one could not ask for better. Railroads run to the north, south, east, and west, reaching all parts of the Republic and the gulf port of Tampico. In addition to these favorable conditions, there is at Monterrey a steel plant and rolling mill. Galvanized iron could be turned out on the spot, and by lowering the cost of all galvanized iron products greatly increase the already large demands throughout Mexico. Several of the largest zinc companies in the States have for a number of years had ore-buying agencies in Monterrey, and now the business interests of that city are trying to arrange for the erection of one or more zinc smelters. Mining interests are also endeavoring to have the National Railway of Mexico construct a line from a point on the Monterrey-Matamoras branch, probably Los Herreros, out through Cerralvo, Sabinas Hidalgo, and on to the main line of the National at Villaldama thus opening up several rich lead and zinc districts, and extensive agricultural sections as well. Partial surveys and some grading were done several years ago on this line.

From a great toll war, which has not been remarkably apparent, though there has been a slight lowering in the

price of oils at certain central points, talk is now switched to an enormous \$30,000,000 merger between the S. Pearson & Son Co. and the Waters-Pierce Oil Co. It is not improbable that such a merger may be brought about, though in the meantime each company is going on with its business and prospecting. After three years of prospecting at Sarlat, Tabasco, in which time 11 holes have been driven, the Pearson people have at last, at a depth of 1730 ft., struck an oil with gravity of only 48. It will burn in the torch without refining. The well flows 40 barrels natural, but is said to pump 500. Another hole will be immediately put down. There is some hope of a railroad to that point, and a refinery as well, as the location at Minantitlan is proving very unhealthy and unsatisfactory.

SALT LAKE, UTAH.

Silver King Ore.—Big Deal in Tintic.—Cole-Ryan and Ohio Copper.

Some significance is attached to the fact that Thomas Kearns, one of the largest stockholders of and general manager for the Silver King Coalition Mines Co., entertained John D. Ryan on his recent visit to Utah. It is surmised that when Ryan was here some arrangement was made by which he could get the Silver King ore for the new smelter. When David Keith, the president, and Mr. Kearns left hurriedly for New York a few days ago, it was taken for

Tintic Smelter.

granted that their trip had something to do with transferring the Silver King smelting contract, which had been made with F. Augustus Heinze, to the International Co. The Silver King has been the greatest silver-lead producer in Utah for a number of years. It is in the Park City camp and its profit distributions aggregate over \$11,000,000 to date. It is now paying 60c. per share annually, in quarterly disbursements, and usually adds an extra dividend during the holidays. The ore blocked out in its workings is sufficient to continue shipments at the present rate for 10 years, and the company owns a large acreage of virgin ground.

Tintic district has done well for the past two years. No other mining district is credited with the same number of dividend payers. The Knights are the largest owners of producing mines in the section, and are in control of a score now being developed. The United States, American, and International smelting companies have sought entrance into Tintic, and have had under consideration the purchase from Knights of the Iron Blossom and Colorado mines, the Tintic railroad, and the Tintic Smelting Co.'s plant. All the smelting companies have made bids for the mines, but do not seem inclined to take the smelting plant, which represents an investment of \$1,000,000. As all three bids have been submitted, the last one by the American, some sort of a deal is expected to be announced within a short time. In the Tintic district a great deal of development work is being carried on, especially in the eastern portion. Small bodies of ore have been found in several properties, and two important strikes have been made in the East Tintic Development mine recently. The Tintic Standard has just purchased ground adjoining the Development company, and will inaugurate an active campaign of development at once.

A large block of the Ohio Copper stock may go to the Cole-Ryan interests. It is known that F. Augustus Heinze's holdings in this property, amounting to the control, have been offered to Cole-Ryan at a nominal figure. The mine has a fine showing from the tunnel level at 1800 ft., to the surface, and would afford a splendid opportunity for Cole and Ryan to get a footing in Bingham.

BUTTE, MONTANA.

May Production. — Reorganization. — Minor Companies.

The Butte mining companies produced 26,443,244 lb. of copper in May. The daily tonnage of ore shipped to the smelters and the total pounds of copper credited to each company for the month were:

Companies.	Tons ore.	Pounds copper.
Boston & Montana	3,520	7,656,000
Anaconda	3,580	6,748,300
Butte & Boston	632	1,154,664
Washoe	530	937,570
Parrot	390	655,980
Trenton	430	735,730
North Butte	1,320	3,445,200
Butte Coalition	1,310	3,039,200
Original	550	1,212,200
Pittsburg & Montana	300	626,400
Miscellaneous	100	232,000
Totals	12,662	26,443,244

The ore of the different companies yielded about as follows: Boston & Montana, 75 lb. per ton; Anaconda, 65; Butte & Boston, 63; Washoe, 61; Parrot, 58; Trenton, 59; North Butte, 90; Coalition, 80; Original, 76; Pittsburg & Montana, 72. The figures of production represent 29 working days.

Among more than a score of new mining companies that were organized in Butte several years ago, less than half a dozen passed through the financial panic unscathed. It is notable that those that did continue work were backed entirely by Western capital. Those that depended on Eastern and foreign money were compelled to suspend operations and have not yet been able to resume. The companies that continued work throughout the financial stress were the Tuolumne Copper Mining Co., the Butte & Superior Copper Co., East Butte Extension Copper Mining Co., and the Butte-Balaklava Copper Co. The East Butte Copper Mining Co., which suspended for some months because of general financial conditions, was first to resume operations, having no difficulty in raising funds even while the general depression continued. A number of other companies have been compelled to re-organize in order to raise money. In this class are the big Davis-Daly Estates Copper Co., the Butte Central & Boston Copper corporation, and the Butte-Montana Mining Co.

There are a number among the less important new companies that did a little work and have since passed practically out of existence. Others never got beyond the organization stage, and there is little likelihood that many of them will soon succeed in raising the money necessary to carry on extensive development. The South Butte Copper Mining Co., owner of a group of claims two miles south of Butte, started development and sank a shaft 328 ft. deep, and then transferred its activities to the Corbin district, where it has a bond on the Daphne group of claims. The British-Butte Mining Co. has been constant in its work on the placer beds west of Butte, and is now operating a big gold dredge. The Eagle Mining Co. has been mining north of Butte and shipping good silver ore. The Butte-Continental Copper Mining Co. is one of the new companies that gave great promise when it was organized, but began too late. It owns a group of claims on the continental divide, east of Butte, upon which there is one large and several small veins. At the bottom of several shallow shafts ore assaying 4 to 12% copper was found. Mining men interested in that section of the country believe that the Continental property is on the same series of veins found in Butte and Corbin districts. Among the other companies that never got fairly started

are the Butte & Buxton, owner of a large acreage of copper-bearing ground 12 miles west of Butte; the Butte Hill Mining Co., North Butte Mountain Copper Co., Butte & Bradley, and several others owning large acreage far north of the proved district of Butte. Outside of the Butte & Bradley, none of these inactive companies sold much stock. Among the great number of companies organized it is remarkable that not more than two or three actually were tainted with fraud. A number failed to 'make good', but they were honestly conducted, and the people who bought their stock may still realize something. With few exceptions none of the dormant companies have any immediate prospects of raising money for an early resumption of work, resumption depending entirely on a considerable improvement in the copper industry and market.

TORONTO, CANADA.

Cobalt Shipments.—La Rose —Dreadnaught.—Otisse.—Gillies Limit. —New Mining Law in Quebec.

The increase in shipments from Cobalt noted during the earlier months of the year was well maintained during April, when 2508 tons were sent to the smelters, as compared with 1317 tons in April 1908. The shipments for the week ending May 22 exceeded those of any previous week this year, amounting to 805 tons, from 10 mines. The Nipissing shipped 226 tons, the La Rose 145, and the Right of Way 129. The figures for the first four months of the year are 9530 tons, as against 5697 for the corresponding period of 1908. Owing to the larger proportion of concentrate, the increase in value will be considerably greater. A noticeable feature of the situation is that the number of shipping mines shows no increase—in fact, the reverse is true. Several mines which shipped last year have so far sent out no ore this season. The increase is entirely due to the heavy output of a few leading mines, especially the La Rose and the Nipissing. These conditions are reflected in the stock market, which continues quiet. The April statement of the La Rose company showed an output for the month of 673 tons, of a net value of \$110,909, which will give a net profit of \$84,115. The earnings of the 11 months ending with April were \$969,584. Raises are being made on the main vein. Good ore is being taken out of No. 2 and 3 raises. No. 4 raise was recently started near the main shaft, and the drills are in high-grade ore. A raise has been made 80 ft. from the McDonald adit to the surface, and is now being worked by open-cut. Development has been begun at the Lawson mine, recently acquired by the La Rose, where driving has been started at the 90-ft. level of the Silver Leaf shaft, following a stringer that is expected to lead to the Lawson main vein. The shareholders of the Rothschild Mining Co. of Cobalt have transferred their holdings to the Dreadnaught Mining Co., now being organized in Montreal with a capitalization of \$1,000,000. It is understood that they will receive share for share in the new organization, which is putting a force of men to work on the property in charge of E. C. Kingswell. The Chambers-Ferland has purchased the Welsh claims in the Gowganda district, on which some good finds have been made. The property is 70 acres in extent and adjoins the Bartlett area.

At the Otisse, in the Montreal River area, work is steadily progressing, and a large quantity of ore has been got out and is sacked ready for shipment on the opening of navigation. The Elk Lake Discovery has a shaft down 103 ft., and when the 150-ft. level is reached driving will be begun. The Elk Lake Cobalt Mining Co., one of the Hawthorne syndicate enterprises, is installing a plant comprising 5-drill compressor, two 60-hp. boilers, hoisting engine, etc. At the Toledo Mining Co. and Cummings Mining Co. properties, in the same district, small air-plants are being put in.

The plans of the Ontario Government as regards the Gillies Limit and Provincial mines may be changed. Recently they advertised for tenders for a portion of the area to be sold in sections, proposing to retain the Provincial mine. Recently, however, they have received an offer of a large amount, which rumor places as high as \$20,000,000, for the whole area, including the Government mine. The precise

nature of the bid has not transpired, the Government continuing to preserve that reticence which has characterized all official dealings with this property. It is admitted, however, that such an offer has been received and is being seriously considered.

A bill embodying sweeping changes in the mining law of Quebec, introduced by Charles Devlin, Minister of Mines, has been assented to by the Legislature. It will have the effect of giving greater security to the discoverer, preventing the blanketing of large areas, and the holding of property undeveloped for speculative purposes, and will encourage capital by doing away with needless restrictions. The bill abolishes the present prospector's license, while recognizing existing rights until January 1, 1910, substituting in its place the miner's certificate, issued on payment of \$10. This entitles the holder to prospect on all lands within the Province, whether public or private, on which the mining rights are vested in the Crown. When a discovery is made the prospector must stake the claim, which in unsurveyed territory must not be less than 40 nor more than 200 acres, and in surveyed territory may be from one up to 200 acres in extent. The Department is to be at once notified of the staking, and within four months from the date application must be filed for a mining license. The application must be accompanied with a fee of \$10, and an additional sum of \$1 for each acre of the claim. The mining license is good for one year, and can be renewed annually on payment of the same fee and acreage tax. Mining land can be purchased at the price of \$10 per acre for 'superior' minerals, and \$2 per acre for 'inferior' minerals, if at a distance of 20 miles from a railroad. If within that distance, the price is \$20 per acre for superior, and \$4 for inferior minerals. Sales are only made subject to the condition that bona fide working of the mine will be commenced within two years, and the patent will only be issued after \$500 has been expended for every acre purchased. The sale may be set aside if these conditions are not fulfilled.

JOHANNESBURG, TRANSVAAL.

Turf Shaft Strikes South Reef. — Conditions of Sinking. — Mining Discussions.—South African Coals.—March Output.

The vertical shaft of the Village Deep (old Turf Mines) has cut what is believed to be the South Reef at a depth of 3756 ft., which closely approximates the calculated figure. At the point of intersection the reef has proved to be very poor. In the mines above, however, it is found that while the South Reef is generally diminishing in value, the Main Reef Leader maintains its grade or even improves with depth. Consequently, the strike of this lower reef, to be made in a few weeks, should prove of great importance and encouragement. The Turf shaft, from which the deepest part of the Central Rand is to be tested and mined, was commenced in July 1906 and followed two bore-holes, reaching the reef in 1901-02. This did much to establish the faith of engineers and investors in the persistent payability of the reefs at deep levels. The shaft is situated 1¼ miles from the outcrop, and is of 7 compartments, with its longer axis at right angles to the strike of the formation. It has been sunk at an average rate of 120 ft. per month with hand-labor, by which means the quickest and cheapest vertical shaft-sinking can be accomplished on the Rand. About 80 natives were employed, and 40 holes (30 to 40 in. deep) were blasted, per 8-hour shift.

The Presidential address delivered by Edgar Taylor before the London Institute of Mining and Metallurgy, in which the lack of papers dealing with the subject of mining in any general sense was deplored, has occasioned considerable comment on the Rand. The statement, so unfortunately correct as regards mining in England or in India, with which Mr. Taylor is intimately associated, is not so true of the Rand today. Mining methods and mining economics have been discussed during the past year with peculiar thoroughness.

Since the Chemical and Metallurgical Society added 'Mining' to its title, many papers dealing with underground problems and routine work have been read by its members.

The S. A. Association of Engineers has also been dealing with mining questions, pure and simple, and even the Transvaal Institute of Mechanical Engineers has been competing in the effort to draw papers and discussions from mining men. Although mining costs in the Transvaal are equal to twice reduction costs, there are certain obvious reasons why the metallurgists and mechanical engineers have in the past been more liberal with their information. From the complex nature of things, there follow more opportunities for change and innovation in surface departments, and there can be nothing more liable to inspire members of technical societies to address their fellows than the discovery of some new scheme of general applicability. The mining man, to succeed, must be full of new ideas and must perceive many openings for improvement, but most commonly these ideas and improvements apply to the particular conditions under his control, and to the minutiae of routine duties. In the case of blasting problems, which concern all mines alike, there has been no dearth of discussion, and all features have been made the basis of debate, from the placing of the hole to the composition of resultant gases. Rand mining men need no special exhortation to make known their ideas, but they hope that Mr. Taylor's efforts may lead to the publication of papers concerning the methods of the many uncommunicative mining companies, whose interests and control are centred in London.

When it was announced that a paper was to be read on 'South African Coals and Their Economies', before the Chemical, Metallurgical and Mining Society, there was reason to hope that a big gap in local technical literature was to be filled. There is no comprehensive description of South African coalfields available, neither as concerns their geological conditions nor their industrial features. The writer of the above paper, Mr. A. Andrews, unfortunately devoted himself almost exclusively to questions of sampling, and he makes us little the wiser on broader questions. The producing districts of South Africa may be roughly classified as those of Natal, Middelburg, and 'Local' (east of Johannesburg). Representative analyses for these districts are given as follows:

	Volatile matter, %	Fixed carbon, %	Ash, %	Evaporative power.
'Local'	16.64	63.02	18.30	11.69
Middelburg	23.03	61.26	13.91	12.64
Natal	25.03	61.09	11.50	13.29

The percentage of moisture runs from 1.65 to 2.04. It may be noticed that the better the quality, the farther the distance from Johannesburg. Consequently the merits of higher quality in the distant coal is offset by higher transportation costs.

The Transvaal gold output for March was 607,000 fine ounces, valued at £2,580,498. This yield is 8000 oz. below the January record, and shows that the industry has not yet recovered from the results of the recent floods. The production for the first quarter has been £7,594,226, equivalent to just over thirty million sterling per annum. Several mines, however, have been forced to hold up stamps lately. The use of new plants now in course of erection at several points, will raise the output for 1909 to a much higher figure. The greatest single-mill output for March was that of the Robinson, which produced £109,375 from 43,302 tons, operating 210 stamps and 4 tube-mills. The Simmer & Jack came second on the list, with £95,277 from 65,600 tons.

In the early nineties the Transvaal Government granted a concession for the construction of a railway from Komati Poort, a station on the Delagoa Bay-Pretoria line, then in process of building, to Leydsdorp, with the commendable idea of doing away with transportation difficulties. The history of the concession is not a savory one, and some of its promoters were afterward condemned to imprisonment in Belgium in connection with the financing. However, the line was surveyed, and completed to a considerable distance, before financial trouble arose, leading to a cessation of work. Then the Anglo-Boer war supervened. Since then, though earnest pleas have been made to the Government to complete the railroad, and so enable the Murchison range to be

exploited, steady refusals have been encountered. Only a small amount would be required, even to extend it northward to join with the Rhodesian railway system, for the principal engineering difficulties have been overcome. The Government is steadfast, and the line appears doomed to dismantlement, for not long ago instructions were issued to pull up the permanent way and lay the rails on the newly authorized Lydenburg line. The main objection to the completion of the Selati railroad is political, even though the contention be admitted that the stretch of country which it has so far penetrated does not offer much promise of railway revenue. The completion of the line would enable Zoutpansberg to import all its requirements direct from Delagoa Bay, a foreign port, at a cheaper rate than by way of Pretoria or from Durban and Cape ports, as at present. As a matter of fact, the Central South African Railways (the Transvaal railway system) would enjoy a longer run, but merchants at Pretoria and Johannesburg, the two chief inland distributing centres, and the coast interests, are vitally concerned in opposing the line. This objection adds redoubled force to the broader controversial point that, politically—which after all is to an important degree commer-

Map of the African Goldfields.

cially—British South African ports ought to be protected, as against the geographical advantage possessed by the Portuguese harbor.

The present transport system in Zoutpansberg is slow and crushingly expensive, and till it is replaced by railway facilities the district cannot hope to go ahead. Endeavors have been made to persuade the Government, in view of the weight of opposition and its own lack of sympathy with the Selati line, to continue the Pretoria-Pietersburg railroad toward the rich copper fields lying adjacent to the Limpopo. Subsequent connection with the Rhodesian Railways at West Nicholson would create a trunk line running from Cape Town and other Cape and Natal coast ports to Broken Hill, in northwestern Rhodesia. A railway association, under influential local auspices and supported by the few mining companies in the district, has been formed in Zoutpansberg, with the object of impressing on the Government the vital needs of communication.

The Murchison range meanwhile lies dormant. Many examples of past mining industry testify to its former state of activity. The fields unquestionably offer rich opportunities to syndicates and tributors of small capital, such as have established themselves within the past two or three years in Rhodesia. Among the largest holders of claims in Leyds-

dorp division today is the H. E. Proprietary, but thousands of claims pegged many years ago are still retained by hopeful licensees.

Klein Letaba, lying to the north of Leydsdorp, was also a centre of some importance as a goldfield contemporaneously with the Murchison range. Among other properties which at one time extracted the precious metal and proved its existence in quantities, but which from exactly the same causes as the Murchison range eventually had to close down, were the Birthday, Ellerton, and Eclipse. At both these centres today may be seen valuable machinery under the supervision of caretakers, waiting patiently for the railway which will again enable shareholders to resume work. The only property at work in Klein Letaba at present is the Louis Moore Gold Mines, Ltd., a small-capitalized Johannesburg concern, which, it is understood, has earned encouraging profits.

It is unquestionably copper which in Zoutpansberg lays chief claim to attention. Over a wide area south of the Limpopo river this is to be found in quantities. Extensive old native workings first attracted notice. As the remoter parts of the district were penetrated, these evidences of ancient industry, taken in conjunction with indications of copper-bearing rock, led to closer investigation. It was only in the latter part of the Anglo-Boer war that any serious attempt to work was made. A concession was then obtained over a large area of ground on the farm Berkenrode, close to the Limpopo river, by John Grenfell. The syndicate formed was later floated into the company known as the Messina (Transvaal) Copper Mines. Stories of ground carrying ore-bearing lodes over a wide stretch in the vicinity of Berkenrode soon after came to hand, and today it is established that nearly the whole of North Zoutpansberg is copper bearing. Numerous syndicates and companies have done a lot of prospecting, notably the M'Tamba Syndicate, a concern owning 1284 claims; the Davidson-O'Shea Coppers, the Stratan Syndicate, and the Seclif-Fischer interests. But it is only the Messina which has gone beyond this stage, and which for some time past has contributed a monthly output of 100 tons. The figure is not large, it is true, but few know the difficulties this company has to contend with. Berkenrode is 150 miles from Pietersburg railroad; all its ore is bagged and sent this distance by donkey wagon transport—the local means of conveyance—at a cost for the return journey of £4 to £5 per ton, the time occupied in to Pietersburg being 14 days. The ore has then to be unloaded and shipped to Delagoa Bay, another 500 miles, and thence to Swansea for smelting. This will afford an idea of what the richness of the ore must be to enable such expense to be incurred and yet leave after extraction process a good working profit. Naturally it was only practicable at first to ship the richer grade, the lower quality being reserved for treatment when circumstances should permit. A few months ago, however, the directorate considered that the state of the mine development justified the erection of a concentrating plant. This has now been installed, and the second quality ore is being shipped after reduction. The mine has been developed on thoroughly sound lines.

It must not be thought that the Messina is the only rich spot in the northern copper region; the limited amount of work done on many other properties, but with less financial support at their call, has shown that the area offers large possibilities to the capitalist, and that several Messinas are only awaiting development. What, however, is crippling these syndicates—a difficulty which only by extraordinary commercial pluck the Messina partly copes with—is the old trouble, namely, lack of railway facilities. Though copper has been principally found in North Zoutpansberg, well defined discoveries have been made in other parts of the district, while Waterberg, in the west, and the Motale fields, though even less explored than their larger neighbor, carry undoubtedly as rich deposits as the Zoutpansberg Limpopo beds. If sufficiently powerful financial interests can be found to exploit the copper region, the provision of railroad communication cannot long be resisted—indeed, there is reason to believe that the current endeavors are not proving wholly fruitless.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Chrome ore is used principally in making ferrochrome alloys and for hardening steel, usually in combination with nickel in the manufacture of armor plates. It is also used in the paint industry, and for fettling copper furnaces.

Hardened copper has probably always been rare. There is no indication that the ancients controlled the art of producing it. A few relatively hard copper utensils have been found, but it is manifest that then, as now, such results were accidental and could not be reproduced at will.

Copper refining electrolytically requires 12 to 15 amperes of current per square foot of cathode surface. The voltage is increased with the number of tanks in the series. The loss increases with high pressure of current, hence a large number of tanks may not be advantageously connected into one series, supplied by one feed wire.

Iron pyrite, even when non-arsenical, is not in demand on the Pacific Coast. Sulphuric acid in the West is now a by-product; the difficulty is to find a market for what might be turned out by the copper smelters. Pyrite is not therefore in request, on account of its sulphur, but if containing copper or precious metals it would be marketable as an ore.

Cinnabar, the chief ore of quicksilver, is readily decomposed by heat, giving off, when retorted with lime, mercury, sulphur dioxide, and calcium sulphide and sulphate. While simple in theory, the practice is difficult, especially with low-grade and impure ores. Those carrying over 4% may be handled in small retorts, but furnaces such as the Hüttner and Scott are necessary for treating those of lower grade.

Mica-trap, or lamprophyre, is an igneous rock, occurring usually in narrow dikes, unaccompanied by tuffs. It is fine-grained and dark in color; it alters readily, and inclines to spheroidal weathering. Abundant brown mica is the porphyritic constituent. Those consisting chiefly of orthoclase and biotite are called minette; those in which the triclinic feldspars predominate in the base are known as kersantite.

Fuel briquettes are usually unsatisfactory, owing largely to their tendency to disintegration while burning. This produces a quantity of fines which partly chokes the fire and partly passes off as unconsumed dust in the draft. The ideal briquette would be one which would exfoliate steadily during combustion. Efforts to produce such a form have been partly successful, but the cost of manufacture has been excessive.

Lead silicate is decomposed in the presence of glowing carbon and of a more stable base, such as FeO. This reaction will occur at moderate temperatures. At high temperature the acid lead silicate is broken up by the CaO, the PbO being set free. This

will be promptly reduced to Pb if a proper reducing atmosphere be maintained. FeO is efficacious in reducing PbO from its combination with silica, even when present in the form of basic or neutral silicates.

Quicksilver faces a decreasing demand, because of changes in metallurgical processes and decrease in hydraulic mining. The more economical methods now applied in the mills also decrease the waste. On the other hand, the actual number of amalgamation mills has increased, and development of the use of the material in making vermilion offsets to some extent the decreasing metallurgical demand. The California output has remained practically constant for twenty years.

Barium in the form of baryta (BaSO_4) is a common accompaniment of lead ores. It is partly reduced to the sulphide in the presence of glowing carbon, and partly through the action of FeS or of metallic iron it is converted into barium silicate, which makes a quite fusible double iron-barium silicate. Much of the baryta enters the slag as a mechanical mixture, without chemical change. As much as 10 to 15% BaO may be driven into the slag. Some barium, as BaS, will also enter the matte.

Tungsten is derived from wolframite, a tungstate of iron and manganese, and scheelite, a tungstate of calcium. Both occur generally in quartz veins cutting silicious rocks, such as granite and rhyolite. Near Deming, New Mexico, scheelite occurs with hübnerite (manganese tungstate), pyrite, and galena in a vein cutting limestone. Near Nome, Alaska, scheelite is found in gold placers in schist. These seem to be exceptions, and in general, search for tungsten is most likely to be rewarded in areas of granitic rocks.

Tridymite is a form of quartz, crystallizing in the triclinic system, but affecting hexagonal symmetry. It is readily recognized by its occurrence in thin, six-sided, colorless tablets, often arranged in stellate groups. It is found only in volcanic rocks of extremely acid composition. It is most characteristic of trachyte, the slab-like forms of that rock being especially likely to contain it. Rhyolites and some few andesites carry tridymite. This mineral is supposed to represent separation of excess silica deposited through the influence of a mineralizer. It is sometimes found accompanying silver ores in Mexico.

Sintering flue-dust and fine ore is practiced to some extent as a means of preparing these materials for smelting in the blast-furnace. Briquetting is also resorted to, using slime, or lime as a binder. Neither method has yet been made universally satisfactory. A large percentage of the sintered or briquetted material is reduced to a pulverulent condition before it has sunk deep in the furnace, and much of it is repulverized in the handling incident upon charging it into the furnace. Both processes are successful with certain ores, depending on their composition. Another method of preparing fines which has been tried consists in mixing them into the stream of reverberatory slag during the skimming of the furnace.

well be considered separately, that is to say, estimate the mining cost on the number of tons mined, including the waste, and the milling cost on the number of tons milled. An objection to this appears at first sight, and that is the difficulty of estimating the amount of ore broken but stored in the mine for filling of stopes. In the cost sheet here proposed the figures are on the number of tons milled. It may be that some of the items could be segregated, such as prospecting and development, in which case they could be joined by a brace.

For different conditions the form will need a different arrangement, but should always be so as to give everyone concerned with its operation a clear idea of what has been done, and to give the management detailed costs.

ALGERNON DEL MAR.

Randsburg, California, May 10.

Mine Inspection and Geological Surveys.

The Editor:

Sir—As I understand your editorial of last week, under the above caption, your position favors a continuance of the prevalent method of administering mine inspection. You manifestly disapprove the tendency to place that work within the jurisdiction of State Geological Surveys. You have hinted, but have not broadly stated, that one of the pitfalls which threatens the efficient enforcement of this kind of police regulation—which mine inspection essentially is—consists in the appointment of young technical graduates, lacking in experience of practical mining. That peril follows administration of the service, whether by bureaucratic or by political methods. The politicians invariably have sons or nephews of their own, or the sons or nephews of friends and henchmen, to care for, and in seeking the appointment of such men they can count upon adding the lustre of eminent respectability through endorsement by the professors at the young men's Alma Mater.

The position of mine inspector is a difficult one to fill properly, and I can say, without fear of refutation, that it seldom has been filled properly in this country. The incumbents have often been better than the position. When the regulations are farcical, inspection becomes a farce, and the inspector an actor in burlesque. There is not in any State today a body of regulations that represents the accumulated knowledge of the Europeans as to what is necessary for efficient police control of safety in mining, nor has the original wisdom of the Americans expressed itself in a new brand of 'dons' sufficient to cover the case. I do not agree that our "politically chosen inspectors" have been "generally successful." They may have succeeded in enforcing a few disjointed regulations so as to avoid an avalanche of political wrath, and some of them have even encouraged reform in matters beyond the range of existing statutes; but they have had no opportunity for successful inspection, because they had inadequate authority. Several coal-mining States have somewhat elaborate regulations, but as a people we are just awakening to the things that should be done

to protect the health and lives of miners. The regulations in those States which contain only metal mines are yet more farcical, and there is no agreement among the States tending to establish standards in matters even of such vital importance as hoisting signals. For example, in both Colorado and Idaho the signal 3 bells means 'men on', this to be followed by the signal for hoisting or lowering, and yet in Idaho there is a station signal, '3—1' bells, signifying 'Station No. 6'.

The American Mining Congress appointed a Committee on Prevention of Accidents in Metalliferous Mines, which will report at the coming session in Goldfield. This should constitute a basis for uniform legislation, if the analysis of requirements found useful in other countries shall prove to have been made in sufficient detail. A consideration of the qualifications and manner of appointment of inspectors should engage the attention of the Congress at the same time. You have pointed out a danger of combining the function of inspection with geological surveys. You have also indicated the need of practical men for the service. Those are proper and useful suggestions, but your claim that political appointment is advantageous and generally attracts men endowed with qualities of leadership must be challenged. The American people are respectors of the law; let the statutes be clear and mandatory as to details, and the inspector need risk none of the compromises involved in leadership; he need only administer his office with tact, and efficient inspection will result. For supervision of this kind the route to appointment should be competitive examination, coupled with requirements as to previous experience in practical work, with continuing examinations to demonstrate competency in the face of the growing complexity of modern practice.

REFORMER.

San Francisco, May 29.

Transportation and Coal Mining.

The Editor:

Sir—I have been much interested in the pertinent editorial appearing in your issue of May 8 on 'Transportation and Coal Mining.' In my opinion, it is regrettable that the 'Commodities Clause' of the Hepburn bill was found not to be constitutional. It is certainly an unfortunate state of affairs when a common carrier is both a producer and seller in the markets to which it is transporting the goods of competitors. This condition invariably brings trouble whether the business is well organized or not. I feel tempted to question the statement about anthracite mining formerly being unprofitable. It may be true that in times past, this was the case for 'outside' miners, although even that is a question when you consider the fortunes made by Cox and other independent producers. However, if it is granted that to the majority the business was unprofitable, what can you say of the railroads, that transported not only their own coal but that of their rivals at prices upward of a cent per ton-mile? Contrast this with the charge made for hauling bituminous coal from southern Illinois to Chicago, one-quarter to one-third

cent per ton-mile. On this rate, the Chicago & Eastern Illinois road was built up and made large profits, and in the past few years four or five railroads have developed lines through this territory to obtain a share of the business at these low rates. Making due allowance for costliness of construction, does not this indicate that the anthracite roads have made and are still making so much out of their hauling that they can well afford to keep the price of anthracite f. o. b. cars low and in this way keep out independent operators? It is a remarkable fact that combination between the anthracite roads in fixing prices has received no check, while such combinations have been so frowned upon in the bituminous fields.

You clearly point out one difficulty that the miners of bituminous coal meet with, particularly in the Middle West; namely, that the trade is a constantly fluctuating one, not only by reason of business, but by reason of the season, everything being arranged for the maximum demand. When a railroad mines only part of its supply, this accentuates the condition. The managers naturally desire to keep their mines running steadily throughout the year, and so provide capacity for the minimum demand. They buy the excess necessary in certain seasons, and unfortunately their greatest demand comes in winter when the commercial mines are already crowded with orders. As a railroad must have coal, this produces complications and frequently coal has to be confiscated. Thus a great contrast results; the railroad mine running every day in the year, the commercial mine practically not running at all in the summer months. This makes it difficult for the commercial mine to keep good miners or indeed any at all. On the other hand, it enables the railroad company, even with indifferent mine-management, to mine its coal at low prices, and having no sales department and general management to maintain, the result is that when the railroad does go out to buy coal, it fixes its price at a point at which the commercial mine often loses money. I therefore think that, with any sort of respectable management, a railway manager can always mine his coal at less than it can be purchased; unless the producer sells at a loss. This condition is very unfortunate, not only for the producer, but for the small consumer, who, in the long run, must pay enough more for his coal to balance the low price of the railroad coal.

Another minor point I venture to question: that the mining of coal by the railroad "eventually leads to selling coal because of the necessity of disposing of certain sizes or grades not wanted by the railroad." This can be taken care of as proposed to be done by the Chicago & Northwestern railroad; namely, by the erection of washeries so that the small sizes of coal can be washed, and in this way put in condition to be used either on switching engines or at stationary plants. If this system were carried out by the various roads, and if they would either voluntarily or otherwise mine all the coal which they need, it would take a very undesirable purchaser out of the market, and would place the railroad mines in the same position as the commercial mines as far as running was concerned. In this way, business would be put on a more stable basis. That it would be dif-

ficult for the anthracite roads, and to a lesser extent the bituminous roads, to withdraw from the mining of coal for the open market is no doubt true, but it is a pity that some way cannot be found to accomplish this, in view of the good that would be done to the coal business throughout the whole country.

So far as the unfortunate condition of the bituminous coal business is concerned, I believe that there is one remedy aside from general consolidations; namely, to increase the difficulty of opening new mines by surrounding them with certain restrictions which would tend to safety and also aid in saving the coal. To be done effectively this would have to be accomplished by Federal laws. As to the possibility of this being brought about by considering coal mining as interstate business, I will not venture an opinion, but that the results would be advantageous, I think cannot be questioned. It would give stability to the business, and by restricting the opening of mines, prices would be naturally improved. The gain from an economic standpoint to both life and property would be well worth while.

GEORGE S. RICE.

Pittsburg, May 19.

How It Strikes an American.

The Editor:

Sir—The letter of Edward Walker and your comments on same, in your issue of May 15, are likely to give a false impression as to the Transvaal mining laws; that is, unless they have been altered since I was there. I think that the reason that the directors of the Cinderella Deep had to get permission to increase their force of underground workers is that the Cinderella Deep has only one shaft and its workings are not connected to those of any of its neighbors. The laws of the Transvaal prohibit the working of a property which has not more than one means of ingress and egress. This prohibition is often relaxed by permission of the State Mining Engineer and under conditions imposed by him.

FRANCIS DRAKE.

San Francisco, May 17.

Salt is classified according to the amount of refining, the methods employed in refining, and the purposes for which the salt is used. The grades are: 'table and dairy', which includes the extra fine and fancy grades prepared for dairy and family use, and all grades artificially dried; 'common fine', including all other grades of first quality not artificially dried; 'common coarse', including all grades coarser than 'common fine' made by artificial heat; 'packers'; 'solar', 'rock', 'milling', 'brine', and 'other grades'. 'Packers' salt is that prepared for the purpose of curing fish, meats, etc. 'Solar' salt is that made by solar evaporation. 'Rock' salt includes all salt mined and shipped without special preparation. 'Milling' salt is used in gold and silver mills. Under 'other grades' are included the low-grade products used for salting cattle and for fertilizers, etc. 'Brine' includes all salt liquor used in the manufacture of soda ash, sodium bicarbonate, sodium hydrate (caustic soda), and other sodium salts or brine sold without being evaporated to dryness.

DREDGING AT OROVILLE.

Written for the MINING AND SCIENTIFIC PRESS
By DOUGLAS WATERMAN.

The Oroville district, California, is an interesting field for studying the various types of dredges and details of operation. There are two distinct types of boats in use. The Risdon type, the oldest in the district, is characterized by an open-connected bucket-line, revolving screen, bucket-stacker, and head-line. The Bucyrus has close-connected bucket-line, shaking or revolving screen, belt-conveyor, and spud. The respective merits of the two is a fruitful

Fig. 1.—Bow-Line Roller Showing Wear.

field for discussion. Each has its champion, with argument that seems convincing—until you talk to the other man. It is indeed difficult to draw comparisons from a yearly record of costs and cubic yards excavated, for the reason that no two boats work under exactly the same conditions; the varying character of the gravel, the age and condition of the boat, and the personal equation of the operatives, are factors which must be taken into consideration. There is a growing tendency among the dredging companies of California to design their own boats, the contract being given to some large manufacturer of dredging machinery; thus we find the Link-Belt, the Marion Steam Shovel, and the Bucyrus compa-

Fig. 2.—Fair-Lead on Boats of Oroville Dredging Co., Ltd.

nies furnishing machinery for boats that combine the best features of both types. This is proving highly satisfactory. As regards the relative merits of the distinctive features of the two types of dredges, the result of my observations is as follows: The shaking screen gives good service where the material is loose and easily washed. On the Pacific boats, the Butte, and others working in loose river gravel, almost free from clay, the shaking screen is entirely satisfactory. The revolving screen is efficient, no matter what may be the character of the gravel; there is no disputing its superiority over the shaking screen when the

gravel is cemented or sticky. The character of a deposit often varies in different parts of the same tract; moreover, the extent of induration, or the proportion of clay, is not always revealed by the prospecting necessary to prove the value of the ground. Therefore the safer course would be to provide the boat with a revolving screen that would meet all conditions. The Oroville Dredging Co., Ltd., operating eight boats, has both types of screens. The shaking screen on one of its boats has recently been replaced by one of the revolving type, at an expense of \$10,000. I am assured by the management that the new boats will be provided with revolving screens. It is a difficult matter to compare the cost of up-keep and lost time with the two types of screens, since the reciprocating parts of the shaking screen may cause unnecessary stoppages through lack of proper attention. The fact that the rolling parts of the trommel require little attention is an argument in its favor. The revolving screen on California No. 3 is a departure from the usual form of washing apparatus. It is telescopic, with three 10-ft. sections, the diameters of which are 6 ft., 5 ft. 4 in., and 4 ft. 8 in., respectively, the largest being at the head, where the greatest screen area is needed. The 4-in.

Fig. 3.—Fair-Lead on Boats of Oro Water, Light & Power Co.

shoulder between successive sections has a retarding influence on the passage of the gravel through the screen, allowing ample time for thorough washing of the material before it is discharged. Manganese rings, 4 in. diam., are placed inside the screen against the shoulder, which is the point subjected to the greatest wear. Longitudinal strips of steel, $\frac{5}{8}$ by $1\frac{1}{2}$ in., are riveted inside the screen. In the largest section there are 24 strips, spaced 8 in. between centres. These strips serve to mix the material as the screen revolves, thus greatly assisting the washing process, as well as the disintegration of the gravel. They also prolong the life of the plates if shifted from time to time, as the portion of the screen under the strip is for the time being protected. As the strips are $1\frac{1}{2}$ in. wide, with $6\frac{1}{2}$ in. of uncovered screen between them, they may be moved four times to a new position on the plate. The strips therefore receive one quarter of the wear, and the life of the screen is increased proportionally. One set of plates in this screen has lasted three years.

While the majority of the operators at Oroville favor the spud, I am of the opinion that equally good work may be done by digging on a head-line. One

argument against the head-line is the surging of the boat, which makes it difficult to hold her nose against the bank. From my observations I judge the intermittent bucket-line, which is found on most boats using the head-line, to be the principal cause of the trouble. The time lost due to changing the head-line, and to stepping ahead with the spud, are about the same. A 5-ft. boat has been digging on a head-line since the spud was broken some months ago, and there has been no marked change in the yardage. At the time of my visit I observed no undue surging of the boat. This is really the best test, being made under exactly the same conditions. The ideal boat would be equipped with both spud and head-line; then if the spud should break, or the winch-men were less familiar with its use, the head-line could be brought into service. While all the boats are pro-

Fig. 4.

vided with a winch which could be used for a head-line in an emergency, it is too light for prolonged hard service.

The point raised in favor of the open-connected bucket-line is its ability to handle large boulders. The close-connected line will perform the work equally well, provided the buckets are properly designed. The angle of the lip should be flat, so that a boulder will rest on top of the lip instead of being jammed between it and the next bucket ahead, which would crush the hood. To allow room for boulders, the pitch of the bucket, that is, the distance between centres of pins, should be greater than that generally given to buckets of the close-connected type. California No. 3 has a bucket that fulfils the above requirements. This bucket has a pitch of 35 in. and a lip-angle of 45°. I am told that by changing from a 5-ft. open-connected to a 3½ close-connected bucket-line, the yardage was increased 30%, and the power bill decreased 25. It is hard to con-

ceive of conditions under which the close-connected bucket-line would not give better service.

The bucket-stacker is found only on the Risdon type of boat, on which it gives good service. These boats are cut away at the stern to allow the tailing to be stacked closer to the boat. A short stacker set at a steep angle will dispose of the tailing satisfactorily. Spud-boats must have a square stern, and therefore require the tailing to be stacked at a greater distance than is necessary with the Risdon boat. The belt-conveyor is superior to the bucket-stacker under these conditions, as a long stacker may be used without putting an excessive weight on the stern of the boat. As regards the relative economy in the use of the two types of stacker, it appears that there is little difference, either in the cost, which includes original out-lay and expense of maintenance, or in the time lost.

A clever idea has lately been applied at the Boston machine shop, which is expected to double the life of the bucket-pins. They are so constructed that the pin and the lug are separate. The lug is fitted into a machined recess in the bucket-bottom as in the past, and is securely riveted; but it has a square hole cut at the point where it meets the pin, the latter having a square end prepared to fit into the hole in the lug. This allows the pin to be turned half round, giving an equal wear to both sides. These new pins have been in use on California No. 2 for six weeks, and so far have shown no wear at the lug.

Nothing is more noticeable than the lack of care given to the bow-lines on many of the dredges. In some instances the deck-sheave was not turning at

Fig. 5.

all; in others, the cable was cutting into the deck or the two rollers (Fig. 1). This means excessive wear on the steel cable, which is costly. Two excellent styles of rope-lead were observed. Fig. 2 shows the device on the Boston and California boats of the Oroville Dredging Co., Ltd. Fig. 4 shows details. From the deck-sheave the rope passes between the two small spools in the carrier, and thence to the 'dead-man' on shore. As the boat swings on the spud the carrier moves from one end of the guide-rods to the other, the idler frame at the same time turning on a vertical axis to accommodate the change of angle. Fig. 3 shows the rope-lead on the boats of the Oro Water, Light & Power Co. This is less expensive to construct than the one just described, and occupies less space on the deck. The device consists of a sheave hinged horizontally to the deck: a semi-circular track, of which the axis of the sheave is the centre; and a carriage attached to this axis by means of an arm, free to turn about it as a centre. The detail of the carriage is given in

Fig. 5. If the rope leads at a sharp angle from the deck to the bank above, the carriage is lifted from the track, resuming its position when the lead is downward instead of upward. A possible improvement in the form of the carriage suggests itself, namely, the substitution of small sheave-wheels for the spools, which would decrease the bending-angle, and lessen the wear on the cable.

The importance of reducing to a minimum the time lost needs no emphasis, yet it is often overlooked by the operators in the daily routine of work. A suffi-

cient number of parts that require constant renewal, such as buckets, pins, etc., should be kept on the boat, ready for instant use. The time that may be needlessly lost by non-observance of this principle was brought forcibly to my attention on a visit to one of the boats. The men had one spare bucket on the boat, which they had just placed in the bucket-line. Another needed replacing, but there was none nearer than at the blacksmith shop, a quarter of a mile away. The day being Sunday, over an hour's time was lost before the teamster could be found and the bucket delivered on board the dredge. A mislaid

looked upon with favor by dredge men in the district. This type of bucket has lately been revived, and I believe that it will supplant the riveted bucket now in use. With the latter, the rivets are continually working loose. Not only do the rivets have to be replaced, but the constant racking of the loosened parts causes serious wear on the bucket, thus adding materially to the cost of up-keep. Leaks occur where the rivets are loose or missing, and loss of gold results. A new cast bucket of 7 cu. ft. capacity was seen at the Pacific shops, which had been carefully designed to combine lightness with strength. The weight of this bucket and the first cost are less than of buckets now in use. The greatest wear on the bucket-bottom occurs on the under side of the rear eye. At the Boston machine shop they are mortising 1 by 6-in. manganese plates into the bucket-bottom to take the wear at this point.

Fig. 7.

the material more evenly. The boats have revolving screens, and the material from the first three gates is directed into these sluices on either side. The sluice-area, which was formerly 1200 sq. ft., has, by the addition of these outside sluices, been increased to 2000 sq. ft. While the percentage of gold lost in dredging is in most cases small, the saving effected by increasing the sluice-area and by installing better washing apparatus would justify the outlay.

The latest dredges at Folsom are provided with a double bank of sluices, which require a larger boat and longer bucket-line than is found in the Oroville field. All the available space inside the boats at Oroville has been utilized for tables; the introduction of outside sluices has gone far toward solving this problem. There is another advantage to be gained by increased sluice-area in addition to the increase in amount of gold saved. Many of the dredges working in loose river-gravel are running below their

Fig. 6.—Oroville Dredge Showing Overhanging Sluice.

Fig. 8.—Protector for Tumbler-Check on Pacific Boats. Indicated by Arrow.

wrench or saw may cause many minutes delay. A clever scheme for keeping track of the tools was observed on the boats of which George Carr is superintendent. An exact reproduction of the various tools was painted in vivid red against the dull lead color of the cabin wall. This was covered when the tool was in its proper place; when missing, the eye was instantly attracted by the painted space.

A bucket-bottom and hood made in one casting is not a new idea. The old Pennsylvania employed such a bucket, but it was unnecessarily heavy and was not

capacity owing to a lack of sufficient sluicing area. To cite an actual case: a boat digging in river-gravel has ample screen-surface, but is limited as to sluice-area. It is now averaging 40,000 cu. yd. per month, which could be increased to 50,000 cu. yd. The cost of handling 40,000 cu. yd. is \$2500, and at this rate the cost of 50,000 cu. yd. would be \$3125. The monthly saving effected by increasing the yardage to 50,000 would be \$625, less a slightly increased power-expense.

The Boston machine shop is employing the Goldschmidt thermit welding process to repair heavy parts of the machinery and the bucket-line. Bucket-bottoms taken from the scrap-pile have been repaired and again placed in service. Broken teeth have been replaced in gear-wheels, and have proved so serviceable that it is the intention of the company to apply the process to the repair of a bull-wheel, broken in three pieces.

A time-saving device for use when changing buckets is the grapple shown in Fig. 7. By this means the chain-block may be instantly attached to the bucket, which is securely held in a position corresponding to the angle of the ladder when raised for changing buckets. The wear on the lower tumbler-cheeks, caused by rocks which have become jammed between the ladder-frame and the tumbler, may be avoided by using a shield made from a piece of old rubber belting, and attached to the ladder-frame as shown in Fig. 8. This device is used by the Pacific boats.

There are a number of features on the various boats which are worthy of brief mention. California No. 3 is provided with an individual ladder-hoist, operated by an independent controller, the advantages of which are: complete control of the ladder when lowering, which is not possible with the friction clutch; no friction band requiring continual adjusting; and the ability to raise and lower the ladder without stopping the bucket-line. This hoist has been in use four years and has not caused one hour's delay. California No. 3 also has a flat conveyor-belt which has given over a month longer wear than the troughed belts, besides reducing the idler cost. If this conveyor were provided with a 48-in. drum, such as is found on El Oro No. 2, the combination would be ideal. Several of the boats of the Oroville Dredging, Ltd., have an 'A' frame which projects in front of the forward gantry. A chain-block may be hung from this frame directly over the lower tumbler—an advantageous position for handling heavy castings. The traveling crane with which El Oro No. 2 is provided saves much time when changing the upper tumbler.

The amount of water actually required by a dredge is an interesting question, but one that is difficult to determine in the Oroville field, since the majority of boats are either working in the river bars, where no water supply is required, or in ponds connected through the tailing with other dredges. California No. 3 worked for months in such a pond. The proportion of solid matter has reached as high as 60 lb. to the ton of water, the increased specific gravity causing the boat to float one foot higher than its

normal draft. This suggests a means for increasing the flotation if the hull be improperly designed, or if heavy parts be added to the dredge. Muddy water is of course undesirable, but the benefit derived from increasing the specific gravity might outweigh the loss of gold and the wear on pumps and machinery. Baggett No. 1 is supplied with 10 miner's inches of clear water. There is a heavy seepage from the dredge-pond through the tailing to a pond at a lower level, from which the clarified water is returned by means of a centrifugal pump. Such a scheme offers possibilities in the way of dredging in countries where water is scarce.

The frequency of the clean-up is important. I was informed by a dredge superintendent that quicksilver could be found in the lower sluices after a week's run, and that it was not safe to run over ten days without cleaning up. When the dredge is started after a clean-up, nothing but gravel should be allowed to pass over the sluices until the riffles have been filled with this material. Sand or clay would pack in the bottom of the riffles and destroy their effectiveness as a means for saving the gold.

Quicksilver Deposit of Huancavelica.—The famous Santa Barbara mine was discovered in 1570. From 1571 to 1908 the output amounted to 51,362 metric tons of quicksilver. During the Colonial period the mine not only supplied the Peruvian mills, but likewise a number of those in Bolivia, Chile, and Mexico. The decadence of the industry dates from 1850, when the Santa Barbara and neighboring hills were practically abandoned, owing, it is said, to the discovery and exploitation of cinnabar in California. The outcrop can be traced from northwest to southeast for a length of 65 kilometres. The width is variable, but at Santa Barbara itself it attains 50 to 80 metres. The formation consists of silicious sandstones, limestones, and calcareous conglomerate, and is dislocated and folded, the strata sometimes dipping northeast and sometimes southwest. Andesites and basalts have intruded this formation, and surround the mercurial deposit throughout nearly the whole of its extension. At the Cerro Santa Barbara, sandstone is impregnated with quicksilver; elsewhere it is in the form of thin stringers in the fissures of limestones or among the conglomerates. The sandstone is impregnated with cinnabar and native quicksilver, as well as with galena, blende, pyrite, and arsenopyrite. The distribution of the cinnabar is quite irregular, but there appears to be a relation between the richness and the andesitic intrusion.—The Mining Journal.

The Belgian steel works of the Cockerill Co., in Liege, have just started an electric-furnace, which is described by G. H. Albert Johnson. The furnace is built on the Girod system, with one electrode, and has a charging capacity of from two to three tons of steel. The dynamos furnishing the necessary electric current—an alternating current of 50 volts—are operated by gas motors, utilizing the gas from the blast-furnaces. The electric furnace is placed in a building in close proximity to the steel converters, with which it is connected by a traveling crane, with a truck for transporting the ladles to the converters.

EARLY COLORADO DAYS.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE W. MAYNARD.

A comparison of the transportation facilities west of the Missouri river in the sixties and the discomforts of the Pullman car of today will be of interest to the newly-fledged mining engineer who makes his first trip from New York to Denver within three days, with only two nights on the road. Harking back to 1864, when I made my first trip, brings out the rather startling fact that I am almost a pioneer, for the discovery of gold by Gregory in the sands of Cherry creek was first heralded in 1859, five years before. While trying to recall the names of pioneer friends, I am also startled by the fact that the majority have 'passed over the divide'. Of those still with us there are William P. Blake, the Nestor of the profession, R. W. Raymond, then U. S. Commissioner of Mining Statistics, whose work carried on under the greatest physical difficulties will long remain an extraordinary example of reliable information and phenomenal industry, and lastly Anton Eilers, the transplanted German, who may be credited with being the father of scientific smelting in the United States.

Of the first instructors in the Columbia School of Mines the only ones left are the beloved Van Amringe and Chandler. I believe I have included in the list those who date back to the sixties, and have been spared to us because they must have discovered the 'fountain of youth'—which is really a cheerful disposition, an outdoor life, and the doing of things which one loves.

My personal experience was not especially novel for those days, and was probably about the same as that of my contemporaries. In April 1864 I started for Colorado to examine a gold mine in Gilpin county. The route was by the New York Central to Chicago, a journey of about two days, thence by rail to Quincy, Illinois, then by boat to Hannibal, Missouri, and from there by the Hannibal & St. Joe railroad to St. Joe, at that time the extreme western railroad terminus in the United States. That railroad ride across Missouri was an eventful one. It was during the rebellion, when the State was only kept from joining issue with the South by the presence of United States troops. The Hannibal & St. Joe railroad was the only means of transportation from the Mississippi to the Missouri, and frequently changed hands, with consequent tearing up of track and destruction of rolling stock. The condition of the road-bed created the sensation which one frequently experiences between Dover and Calais. On the first night, just before the berths were made up, we were startled by the discharge of rifles, and the smashing of glass on one side of the car. The passengers suddenly became very tired, and reclined on the car floor. The engineer threw open the throttle, and that tired feeling gave place to an expectation of speedily being wrecked. The guerillas must have been widely distributed along the road, for on the following morning, on our arrival at a station, we saw ten or a dozen laid out on the station platform who had been killed by Union scouting parties.

After a night at St. Joe we crossed the Missouri to Atchison, Kansas. The town and the surrounding country were covered with prairie schooners, horses, mules, oxen, shouting teamsters, women, and babies, all headed for 'Pike's Peak or bust'. The overland stage line at that time was owned by Ben Holladay, and the fare to Denver was \$125, which did not carry with it a guarantee as to time of arrival. The stage coaches were the well known Concord thorough-brace type. For comfortable riding the stage had to be heavily loaded. Our load consisted of nine persons inside, three on a seat, and four or five on the roof. In addition to this, there was a heavy mail in leather sacks, and considerable express matter at 50c. per pound. The mail for the most part consisted of public documents, and contributed to the profanity of the driver and passengers. In subsequent trips I have frequently seen the mail sacks with their contents used to fill a chuck-hole in order to get over a bad bit of road.

It was my fortune to be the middle man on the back seat, and I had eight days and seven nights of it. The only relief was when we could stretch our legs during the change of teams at feeding stations. The uniformity of the food—fried bacon and hot biscuit, the latter yellow with soda—gave no indication as to whether the meal was breakfast, dinner, or supper; this could only be determined by the time of day. The distance traveled to Denver was 653 miles. The route from Atchison was northwest to Fort Kearney on the Platte river. At the time of our arrival there was an encampment of Sioux and Arapahoes, fully a thousand in all, who had gathered to receive the annual distribution of blankets and food from the Government. There was a large Government wagon-train and a liberal sprinkling of soldiers. On the following June these same Indians were killing people all along the line. On my return trip we frequently had to travel 50 to 60 miles with the same team, because at the relay stations the inhabitants had been slaughtered and the horses and mules driven off. During the eight days and seven nights wagon-trains were always in view, the larger number being drawn by oxen. About three days from Atchison, dead oxen began to deface the landscape and vitiate the atmosphere, and were in evidence all the way to Denver.

I doubt if a shipwrecked crew ever rejoiced more on reaching land than did our load of jolted companions on being landed at the Overland Hotel in Denver. My recollection is that all of our passengers were 'tenderfeet', and they soon began to make remarks unfit for publication, about the rooms, beds, and food, instead of contrasting the eight days' agony with the relative luxury of that hotel. The proprietor, like the historic church organist, was doing the best he could, and really did not deserve to be shot.

The population of Denver was about 2000. The residences were one-story frame buildings scattered apparently without regard to the location of prospective streets. There was but one brick building, the United States Mint, which was in fact only an assay office for bullion and gold dust. It was a great boon to the miner, for there he always got the full

value of his deposit. At Denver myself and companion were so fortunate as to meet James E. Lyon, of the Central City firm of Lyon, Pullman & Towne, who invited us to make the house of the firm our home while in the mountains. With a letter of introduction to Mr. Towne, we were cordially received and cared for during our stay.

The last stage of the journey was the 40-mile drive to Central City. The first 15 miles was across the level country to Golden City, at that time the capital, standing at the base of the foot-hills of the front range of the Rocky Mountains. Then followed the climb through canyons and along the banks of the roaring Clear creek, and over Guy hill, where the road to our Eastern eyes appeared to be little short of perpendicular. 'Jake', the famous driver on the route, guided his six horses with a confidence and ease which elicited hearty approbation from some of our Jehus who had 'tooled' a coach on the level roads of the East.

Pat Casey (a road above town still bears his name) is reputed to have been the first Colorado man to sell a mine in the East, but it is not generally known that the next sale was that of the Gregory Consolidated by Lyon, Pullman & Towne, for \$500,000. The Pullman of this firm was George M., who put his third of the money into building sleeping cars, and thus his start in that great business came from a Colorado mine. It is stated that this was his first and only mining venture.

My work at Central City was confined to the examination of some prospects in Eureka and Prosser gulches, in the neighborhood of the Gunnell lode, which had already become celebrated. After visiting many of the principal mines and stamp-mills in the neighborhood, I was so favorably impressed with the general outlook that I concluded to establish a branch engineering and assay office.

On my return journey to New York, I stopped off at Denver, and on the night of my arrival I witnessed a flood which cut a swath through the centre of the town. The flooded condition of the surrounding country delayed the departure of the stage for a day or two. It was on this return trip that we witnessed the ruin wrought by the Indians.

In the following December I started out, with one companion, this time going from Chicago by the Chicago & Northwestern railroad, to Des Moines, the extreme western extension of that road. From Des Moines we staged it to Council Bluffs, and crossed the river on the ice to Omaha. It was our intention to buy a team and carriage and drive to Denver, trusting to be in daily contact with overland wagon-trains. The military authorities at Omaha dissuaded us from taking the risk, on account of the Indians along the road. We therefore took to the Ben Holladay coach, and finally brought up at Fort Kearney, after crossing the Platte partly in a flat-bottomed skiff and for most of the distance by wading through floating ice.

At Fort Kearney we caught the overland stage for Denver. The other passengers were frontiersmen, all armed—in fact, the coach was practically an arsenal. We had a six-mule team and I sat with the driver. When nearing Plum creek he made the rather

startling announcement, "There are Indians somewhere around here." "How do you know?" I asked. He answered, "See the way them leaders are acting. A mule can tell when there is an Indian a mile away."

We were paralleling a range of bluffs a mile or more to our right when we saw Indians on ponies bobbing up and down on the other side of the bluff, trying to keep up with the coach without exposing themselves. The driver, who had had some Indian experiences, 'got a move' on the mules, which was a surprise to them and the passengers. As we were approaching a military post west of Plum creek, the Indians gave up the chase. Within about two miles of the post we encountered a gruesome sight—the wreck of a wagon-train and the bodies of the teamsters, shot to death, and many of them with arrowheads buried in their bodies, and all scalped. One of the men was still breathing; so a member of our party mounted a mule, rode to the post, and returned with an ambulance and surgeon. I learned subsequently that the man's life was saved.

For a part of that winter we 'bached it' in a log cabin in Prosser gulch. On the receipt of the assay outfit, which had been on the road for three months, I established an engineering and assay office, the first one in Gilpin county. There was great activity, both in mining and custom-milling, as long as the gossan ores held out. When the sulphurettes were reached and the values could not be saved by amalgamation, the outlook became gloomy. Then came an epidemic of processes invented by fake scientists who were absolutely ignorant of the first principles of metallurgy, and these not only got a hearing, but money in large amounts, from Eastern men, for the installation of worthless machinery. R. W. Raymond in one of his reports calls attention to "the *outcrops* of process machinery scattered over Gilpin and Clear Creek counties." In the meantime young metallurgists who had been trained in Germany began to arrive in New York, but could not get a hearing on the established methods of ore treatment.

A serious handicap during the pre-railroad days was the high rate of wages and supplies. Miners received \$5, blacksmiths \$10 and \$12, and carpenters the same rate per day. The food-supply was uncertain, for very little was raised in the country, apart from chickens and eggs, and these brought very high prices. All the flour and bacon came from the East. When a snow blockade occurred refuge was taken in canned goods. That the people were able to pull through under these conditions is good evidence of the general value of the ore.

As many of the mines began to produce copper sulphurettes in depth, with increasing gold values, the necessity of resorting to smelting became evident. The nearest coal mines were in the foot-hills north of Golden, 30 miles distant, and, there being no railroad, it was manifest that a smelting plant near the mines would necessarily be restricted to wood for fuel. After many abortive efforts, James E. Lyon built a small reverberatory furnace at Black Hawk, presumably from his own design or from that of a mason. The roof promptly fell in on the first firing;

therefore smelting was declared to be unsuited for Gilpin county ores.

In the summer of 1886, N. P. Hill, professor of chemistry in Brown University, arrived in Central with some students, on a vacation outing. While in Central he passed many of his evenings in my office, and naturally our conversations were for the most part metallurgical. I told him of the German and English methods of treating ores of the same character as those of Gilpin county. He became so interested that he concluded to try to secure capital among his Boston and Providence friends, with the view to erecting a small plant at Black Hawk. I advised him to visit European plants in advance of undertaking the erection of a plant, in order that he might fortify himself by personal observation. I furnished him with the names of the principal plants in Germany and Wales.

The outcome of his investigation was a visit to the Swansea works of Vivian & Co., where Hermann was manager. He arranged with the owners of this plant to loan him Hermann for a period long enough to erect one furnace at Black Hawk. Pending the installation of a chemical laboratory the assays and analyses were made in my office. The name of the company was the Boston & Colorado Smelting Works. The plant was established in 1867 at Black Hawk on North Clear creek. The officials were N. P. Hill, resident manager, Henry R. Walcott, business manager, and Professor Beeger, metallurgical superintendent. Beeger was later succeeded by Richard Pearce. These works were the forerunner of the great Argo plant near Denver; a monument to Richard Pearce's metallurgical ability and untiring industry. The metallurgists of the present day know little of pioneer work in furnace construction.

The opportunity for bringing the mineral resources of Colorado to the knowledge of the outside world presented itself in the exposition which was to be held in Paris in 1867. Meetings were held in Central and Denver, with the intention of trying to impress upon the mine-owners the importance of making an exhibit which would be creditable to Colorado. The miners and mining companies as a whole did not appreciate the importance of such an exhibit, and it was only by persistent entreaties and many a journey by wagon and by saddle, nearly a year's work, that a representative collection of ores was secured. Assays of the typical ores were made without cost to the contributors. The heavier exhibits were carried to North Platte, the then terminus of the Union Pacific, in wagons which were returning to the railway. The most valuable samples were carried by Wells Fargo & Co. without charge. The railroads all the way to New York were equally liberal, with the exception of the New York Central & Hudson River, which held up some cases with a freight bill for \$64.

In Frank Hall's 'History of the State of Colorado' the following statement appears in Vol. I: "In 1867 George W. Maynard, a mining engineer, was appointed by Governor Cummings, Commissioner for Colorado to the Paris exposition of that year. The appointee being unable to go, declined, when acting-Governor Hall tendered the place to J. Parker Whitney, of Boston, who being largely engaged in the development of our mines signified his willingness to

accept, and also to collect a fine exhibit of rare and representative minerals to be added to his already superior cabinet, and take them to the exposition at his own expense. The effect of this representation was salutary, for it induced many eminent scientists of Europe to make exhaustive examinations of the gold, silver, and other resources of the Territory, whose favorable reports when published caused the investment of much foreign capital in them."

While Mr. Hall is correct as to the final outcome of the exhibit it is not accurate as to the details which preceded the installation. I was appointed Commissioner by Governor Cummings, the engrossed commission was countersigned by the Secretary of State at Washington, and the great seal of the United States was attached. At the time of the appointment the Territorial Legislature was not in session, so that an appropriation for the expenses of the Commissioner and the cost of installation could not be made. It therefore devolved upon the citizens of the Territory to supply the funds. A finance committee was formed, of which George Clark of the banking house of Clark, Gruber & Co. was the chairman. Meetings for the collection of funds were held in Denver and Central with unsatisfactory results.

In December 1866 I left for New York so as to receive the ores on their arrival and arrange for the shipment to Paris, on the assurance that the necessary funds would follow. Shortly after reaching New York I received a letter from Mr. Clark stating that he had been able to raise but \$300, and that if I would go to Paris and set up the exhibit he thought an additional amount would be forwarded. This liberal financial proposition was my reason for declining to go. As there were several Colorado men in New York and Boston, who had sold their claims, and others who were working mines in the Territory, I called a meeting at the St. Nicholas Hotel, which was fairly well attended. The only response I got at the meeting was the offer of James E. Lyon to pay the New York Central & Hudson River railroad freight bill if I would turn over the ores to him to be set up in his office. This I promptly refused to do.

My next effort was to get Boston interested. Finally, just as I was beginning to despair of raising the necessary money, J. Parker Whitney, of Boston, called on me and offered to meet all the expense of installation of the exhibit if I would have him appointed Commissioner in my stead. He frankly stated that his proposition was not purely eleemosynary, for he expected that on the strength of his position he could influence foreign capital to invest in Colorado. I immediately took the steps which resulted in the appointment of Mr. Whitney. I do not know if the Territory ever officially recognized Mr. Whitney's valuable services. I furnished him with a list of the ores and the names of the contributors, the mines, and the districts, with condensed descriptions, as well as the assays of the typical samples of ores. Mr. Whitney published a pamphlet in English and French, the title of which is: 'Colorado, in the United States of America; schedule of ores contributed by sundry persons to the Paris Universal Exposition of 1867, with some information about the

region and its resources.' By J. P. Whitney, Commissioner from the Territory.

The pamphlet consists of 7 pages of assays, 66 in all, together with the names of the mines and their owners, followed by subdivided lists aggregating 415 from different districts, each subdivision with the caption, 'Ores Contributed by J. P. Whitney'. Doubtless Mr. Whitney contributed from his own collection some of the specimens, but in checking the lists I find that by far the largest number were contributed by the mine-owners and were packed and shipped from Central City.

In the 'Report of the United States Commissioner to the Paris Exposition' (Vol. II, pp. 44, 45, 46) is the following statement: "Mr. Whitney published a pamphlet in English and French descriptive of the Territory and its resources, with a list of the principal districts and claims. A gold medal was awarded for the representation by the jury."

In the *American Journal of Mining* (July 27, 1867), of which R. W. Raymond was editor, is the following editorial: "The collection of minerals sent from Colorado to the Paris Exposition has won, as it deserved, a gold medal. It was complete and splendidly arranged, accompanied with assays, maps, and descriptions, in English and French and German, of the resources of Colorado. The Coloradans are congratulating themselves on the result of their experiment, which, it is said, is already bearing fruit in the way of increased attention on the part of foreign capitalists to that portion of the United States. Mr. J. P. Whitney, the Commissioner from Colorado, receives much credit for his connection with the enterprise. We take the liberty of calling the attention of our friends in Colorado to Mr. George W. Maynard, late of Central City, as the individual to whom their thanks are chiefly due for the thorough arrangement of the collection which has won such favor abroad. The fact is, Colorado need not boast of public spirit in this connection. If we remember aright, Messrs. Maynard & Martine made all the assays of these minerals and arranged the entire collection. In return for this the citizens failed to respond to the movement inaugurated by the Governor, for sending Mr. Maynard as Commissioner. The Governor was finally obliged to substitute the name of Mr. Whitney, who went at his own expense, and deserves all the glory he has won, for his public spirit. Meanwhile Mr. Maynard, who had received no reward for the expenditure of considerable time and money, should at least share in the credit of the triumph, and we are persuaded Mr. Whitney would be the first to accord him that praise which is fully his due."

The suggestion of Mr. Raymond as to the recognition of the preliminary work in Colorado was not acted upon by Mr. Whitney, for there is no reference to it in his pamphlet. The gold medal was awarded to Mr. Whitney, instead of to the Territory, and has not been turned over to the Territory. I have frequently brought this matter to the attention of the Governor and other State officials, but have not been able to create any interest in the matter.

It is pleasant to note that several of my fellow students at Chausthal became my assistants in Central City, among them Hermann Stoelting, who lost

his life in the wreck of the *Schiller* on the Scilly Isles. Wolters and Huepeden, who subsequently held important positions in Idaho and Montana, were also assistants of mine. Charles A. Martine, who began his career as assistant to Professor Joy, at Columbia, finally came to Central City and was my chief assistant for a year previous to my departure for New York. He succeeded to my business as assayer, and subsequently settled in Georgetown, where he became very successful in mining and in the development of new methods for the treatment of silver ores. He died greatly regretted by the entire community.

Central City, Idaho Springs, and Georgetown differed greatly in the character of their inhabitants, from the mining camps farther west. I recall but one case of shooting in Central during the three years of my residence. As a rule the miners and all the laboring men were a superior class, and to the prospectors is due the credit of having made discoveries which finally resulted in the development of some of the most important mines which have been worked to the present day. The majority of the mine superintendents, mill-owners, and merchants, were cultivated young men from Boston, Providence, and other Eastern cities, who came to Central with their wives, so that there was a really refined society. A circulating library was established, to which Harper & Bros., D. Appleton & Co., and other publishers contributed. George Bancroft, the historian, presented a complete edition of his works. Three or four religious bodies were well represented, so that there was a general observance of the Sabbath. Many of the 'old families' of the present day in Denver had their beginnings in Central City.

EMERALD MINES IN COLOMBIA.

Until 1830 all the emeralds in the market came from Colombia. Since that time 10% have come from the Ural Mountains and Norway. Some good-sized stones, though not free from flaws, have been found in Alexander county, North Carolina. No emerald mines are known in Mexico or Peru, and those that the Spanish conquistadores first brought from the latter place doubtless originated in Colombia. Later they discovered the real source. To this spot, known as Somondoco, in the department of Boyaca, lying about 125 m. from Bogotá, the Spaniards were brought by the Indians; and an account is extant of how Pedro Fernandez de Valenzuela made the journey, and extracted the stones from the calcite veins in which they commonly occur. At Muzo the jewels are still obtained from excavations in a dark bituminous limestone, which rests on clay shales containing ammonites, showing it to belong to the Lower Cretaceous. From Muzo also is obtained the rare amber colored fluocarbonate of cerium, called parisite from the name of its first discoverer. Its brittleness renders it of little value as a gem stone, but it is a prize to the mineralogist.

Tin is found in the Black Hills, but has only been produced in small amounts. The output from the United States is insignificant, forming less than one per cent of the world's output.

ALASKA BUILDING, A.-Y.-P. EXPOSITION.

Herewith is presented a view of the Alaska building at the Alaska-Yukon-Pacific Exposition, now opening at Seattle. The building has 36,000 sq. ft. of floor space, which is taken up by exhibits that admirably represent the resources, industries, scenery, and general features of Alaska. As wall-decorations there are panoramic views of the coast range, the glaciers, mining operations, and scenes on the Yukon. There are relief maps, geologic exhibits, mineral specimens, ores, gold bullion, and miniature operations that represent the mining industry of the Far North. The forestry of that country is represented by sections of trees; the fisheries and the fur interests are being well displayed, and when the season is further advanced there is to be an exhibit of flowers and flowering plants from the banks of the Yukon. Paintings by Alaskan talent and artistic work in woman's department will also be attractive features. Alaska has much to show, and the exhibit will com-

GEOLOGIC NOTE ON LIBERTY BELL.

Written for the MINING AND SCIENTIFIC PRESS
By AN OCCASIONAL CONTRIBUTOR.

The Liberty Bell mine, at Telluride, Colorado, lies chiefly within the San Juan formation of indurated andesitic tuffs, but extends through into the underlying quartz-conglomerate, which is of doubtful Eocene age. The displacement of the walls at the contact is about 100 ft. where explored, the hanging-wall contact being the lower, as the fault is normal. There have been at least two important movements along the fault-plane, each followed by mineralization. The older vein-filling is quartz, which in places cemented the broken wall-rock into a hard tough breccia. This quartz is characterized in general by an equality of value between the gold and silver, taking the latter at 50c. per oz. After the quartz was deposited a second movement of the fault opened cavities, which were filled by calcite.

A third period of enrichment, of less importance

Alaska Building, A. Y. P. Exposition, Seattle.

mand the attention and admiration of thousands of visitors to the Exposition who are unable to visit the country itself.

A new zinc-lead concentrating plant, with a capacity of 1000 tons of ore per day, has been erected by the Humboldt company, Bleischarley mine, upper Silesia. The plant, which is operated electrically, comprises six sets of washers, averaging 170 to 180 tons each per day, the rich intermediate products from these being further treated in two small sets, and the low-grade intermediate products in two large sets of apparatus. The slime-washery is fitted with six washers, with two separate sets for treating the mixed slimes recovered from the waste water and settling tanks. The products are handled in narrow-gauge trucks, which are shunted by electric locomotives and hoisted to the tipples at the storage bins by electric lifts, similar lifts being installed at the waste heap. The consumption of power is about 1600 hp., distributed through 17 electric motors. The total cost of treating the ore, including labor, supervision, and keep, will be less than 30c. per ton of crude ore.—*Oesterreichische Zeitschrift für Berg und Hüttenwesen.*

than the other two, was one in which gold and a little lead were deposited in the joints and cracks of a broken zone at the juncture of the main vein with a branch vein in the hanging wall. No silica or calcite accompanies this enrichment, and large blocks of what looked like waste rock were shown by assay to be rich ore. There is in general an approximately horizontal distribution of values in the vein, resulting doubtless from the nearly horizontal bedding of the tuffs in which it lies. This condition is modified, of course, by the distribution of the ore-lenses, which do not lie horizontally, but pitch at various angles in different parts of the vein. It can readily be understood then that, with these conditions borne in mind, valuable hints could be obtained from a study of the map.

The asphaltite deposits in Eureka county, northeastern Nevada, about 15 miles south of Palisade, have been recently studied by Robert Anderson of the U. S. Geological Survey. This occurrence is interesting, for no asphaltite deposit has heretofore been found in Nevada. The asphaltite fills fractures in steeply dipping Carboniferous strata.

RAY COPPER DISTRICT, ARIZONA.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM H. TRUESDELL.

The Ray district in Arizona is of great scientific and economic interest. Its prospect of importance as a copper-producing district makes the subject of the local geology pertinent. Ray is situated on Mineral creek, about five miles north of Kelvin, on the eastern border of Pinal county. It lies in an area which has not yet been mapped by the U. S. Geological Survey, being just outside the eastern limit of the Florence topographic sheet, and $5\frac{1}{2}$ miles south of the southwestern corner of the Globe quadrangle. Dripping Spring range is the name locally applied to the mountain ridges in the area, but there seems to be no definite boundary between these and the Superstition range to the northwest. The valley of Mineral creek lies between two ridges having a northwesterly trend, the width at Ray being approximately four miles, and the altitude of the town about 2200 ft. The slopes of the western ridge rise to 4000 ft. at the northern end, the crest gradually falling away to the Gila river. The eastern ridge rises 300 to 400 ft. higher. Mineral creek has a bed of even grade to the Gila river at Kelvin. At Ray a group of irregular hills, distinguished by their reddish color from the surrounding country, forms the lower part of the slope of the western ridge. They rise to a height of 400 to 500 ft., and cover an area of about two square miles. A correct idea of the age and character of the formation composing these hills is important, as it is in them that the deposit of chalcocite is found.

The formations of the Globe quadrangle, which are represented in the Ray district, are given in the table below* which will serve as a geological summary:

SEDIMENTARY ROCKS.

- Quaternary.
 - Alluvium.
 - Gila conglomerate.
- Tertiary.
 - Whitetail formations.
 - Devonian-Carboniferous.
 - Globe limestone.
- Cambrian.
 - Apache group. Dripping Spring quartzite.
 - Pre-Cambrian.
 - Pinal formation (schist).

IGNEOUS ROCKS.

- Quaternary.
 - Basalt flow.
- Tertiary.
 - Dacite flow.
- Mesozoic.
 - Dikes of diabase and diorite-porphry.
- Pre-Cambrian.
 - Dikes of quartz-porphyrines.
 - Granular and porphyritic types of granite and diorite.

The Pinal schist, as described in the Globe quad-

rangle, consists of metamorphosed silicious sediments of pre-Cambrian age. The formation in the hills at Ray is considered to represent the Pinal schist, but it has undergone less metamorphism, and bears a closer resemblance to the partly metamorphosed grits and sandstones described in the Globe area. In a straight line, it is only 7 miles to the nearest area of Pinal schist in the Globe quadrangle. At Ray, the formation passes from laminated quartzite, through quartz-schist to sericite-schist, according to the distance from the contact with the intrusive granitic rocks. The small dikes of quartz-porphry had little effect in producing the schistosity. At the southeastern edge of the exposed beds, along the west side of the creek, some distance below the bridge, the sediments are least altered. At this locality a gray quartzite is found, with laminations about two millimetres thick, of small white quartz grains. Disseminated grains of copper sulphides give a greenish-gray tinge to the rock.

On the hill above the Ray shaft, the rock is more schistose and the color is pinkish-purple, from the presence of iron oxide. Another variety is that in which the structure is more massive, with curved laminations. In the northwestern part, as the contact is approached, where the sediments have been most crumpled and contorted, the rock approaches the character of a sericite-schist. It is a much-jointed gray rock, with platy laminations, having a finely crystalline appearance.

Study of thin sections shows the chief difference between these beds and the Pinal schist of the Globe quadrangle to be in an absence of re-crystallization of the original grains, and an absence of secondary accessory minerals. Mica has not been developed to aid in the production of schistose cleavage. Microscopically, the rock is seen to be composed of quartz grains in which no originally fragmental character is apparent. There is a tendency to parallelism shown in the arrangement of grains in layers of the same size, alternating with those of different sizes. While some of the larger grains appear to have been crushed, there is no flattening, nor is there any secondary enlargement of grains. For the most part, the only effect is that produced by incipient mechanical crushing, though it is possible that some areas not inspected may yield evidence of greater metamorphism. A mica-schist of true crystalline character, which is doubtless the Pinal schist, is exposed on the lower slopes of the eastern side of Teapot mountain, but its relation to the area under discussion is obscured by overlying gravel.

The intrusion of the granitic batholiths produced a notable effect in disturbing the position of the beds. Their induration was caused at the same time, so that erosion in bringing into relief the harder ledges aids in defining the limits of the different disturbed blocks. The irregular attitude of some of the hills, with thin steep scarps, suggests faulting. It would be difficult to estimate the amount, and would require a close study of the planes of schistosity and jointing. There are bands of greatly shattered breccia included in the formation. The period of brecciation, and whether movement occurred along these planes, have not been determined. In the northwestern part of

*Professional Paper No. 12, and Folio No. 111, U. S. Geological Survey.

the area, near the contact with the Schultze granite, are to be found the greatest effects of the intrusion. The crushing which the beds have undergone has crumpled and contorted them to a high degree. The direction of the schistosity varies in a small space. The district is not favorable for finding actual contacts with the granitic intrusives. The fact of intrusion is to be made out by the contorted condition of the schist, and the porphyritic facies of the granite near the contact. The same difficulty arises with respect to finding evidence of the unconformity between the Pinal formation and the Dripping Spring

ledges. Some of the beds are of fine-grained white quartzite, while others are composed of a coarser grit, cemented by hematite, giving a reddish color to the rock. The Globe limestone, a gray to black, compact rock, cherty in places, overlies the quartzite, and is apparently conformable. The upper part has been removed by erosion, but 250 ft. still remains. For a long distance down the slope, in the direction of Kelvin, it forms the summit of the ridge. The upper eroded surface is quite fossiliferous, containing brachiopods, cup-corals, and crinoid stems. A few imperfect specimens were identified as Carboniferous forms.

Excluding the hills of the Pinal formation, the western ridge is carved from several types of granitoid rocks. Commencing at the southern edge of the hills, composed of Pinal sediments, a gulch heading toward the conical peak south of Teapot mountain, and the Copper canyon road, appears to mark the boundary of the formation. On the south side of the gulch a black copper-stained, slaty quartzite extends southward until it is covered by the Gila conglomerate. A little to the west outcrops of granite are

Map of Ray District.

quartzite on the eastern side of Mineral creek. As the Pinal formation crosses the creek into the lower part of the town, there is difficulty in distinguishing it from blocks of the latter formation brought down by faulting. The Dripping Spring quartzite and the Globe limestone form the mass of the eastern ridge. The presence of the lower member of the Apache group, called the Pioneer shale, was not ascertained, but as 700 to 800 ft. of the assigned thickness of the group (800 to 1000 ft.) is exposed in the section on the ridge, a closer examination may prove its occurrence at the base of the quartzite beds. The upper member, or Dripping Spring quartzite, forms massive projecting

Structure of Ray District Along Line A-B.

found. It is a fine-grained grayish rock, with green hornblende, which on weathered surfaces appears in the form of black spots. Apparently cutting this to the north is a medium-grained light-colored biotite-granite. This occurs about one-eighth mile west of the hill on which the Ray shaft is situated. At a point about a half mile north of Kelvin an exposure of granitic rocks is found for a distance of a quarter mile along the tramway. There are two types; one is reddish, has much biotite and large pink feldspars, and is silicified in places. The other is a holocrystalline grayish-white rock, with a grain of 2 to 5 mm. diam. Its components are abundant feldspars, what appears to be fibrous green hornblende, and a small amount of clear quartz in rounded grains up to one centimetre in diameter. Microscopically, there is more groundmass than would be expected. The feldspar is much altered, but a large proportion is evidently plagioclase. No original hornblende appears, the areas being now filled with chlorite and magnetite. The rock is probably a diorite, and resembles some types of the Madera diorite. At the eastern base of Teapot mountain a granitoid rock is exposed which is also doubtfully classed with the Madera diorite, the proportion of plagioclase being hard to estimate, due to alteration. It is a speckled greenish-black and white rock, with a grain of 2 to 3 mm., composed of white plagioclase, greenish-black hornblende, small amount of biotite, and still less quartz. There remains to be considered a mass of granite-

porphyry on the northwestern edge of the Pinal formation, bearing evidence of an intrusive character. The porphyritic facies occurring near the contact resembles closely the similar facies of the Schultze biotite-granite in the Globe area, with the exception of the smaller amount of biotite in the former. The noteworthy characteristics of the granite-porphyry at Ray are the large phenocrysts of perfect orthoclase crystals, and the quartz phenocrysts. The former are flesh-colored and reach a length of 6 cm. Many are twinned after the Carlsbad law. The quartz tends to crystallize in bi-pyramidal forms up to 1 cm. long. The ground-mass contains numerous small crystals of pink orthoclase in a finer greenish-white paste. Hornblende occurs sparingly. A thin section shows the typical fabric of a quartz-porphyry, which, as remarked in the Globe folio, would not be expected in a rock of this crystalline character.

Pre-Cambrian dikes and intrusive masses in the Pinal formation are not very prominent, because of their similarity in color to, and lack of contrast in hardness with, the Pinal sediments. In the northwestern area a few dikes of quartz-porphyry occur. They have a pink felsitic ground-mass, with small white opaque feldspars. Quartz phenocrysts occur sparingly, rounded by corrosion and averaging 3 to 7 mm. in length. In one dike phenocrysts are absent. Thin sections show the feldspar greatly altered, and exhibit the ordinary type of quartz-porphyry. On the hill above the Ray compressor-house a larger irregular mass of the same type is exposed. In the thicker parts it carries some biotite, and the texture approaches that of a granite-porphyry. One or two dikes radiate from this mass. On the eastern side of the creek, at the base of the slope just north of the Arizona Hercules buildings, is an outcrop of fresh biotite granite-porphyry, intrusive in hard quartzite, having a vertical irregular schistosity. The dikes and irregular masses are probably connected with the Schultze granite-porphyry.

Diabase and diorite-porphyry dikes, of post-Carboniferous age, are more prominent and numerous on the eastern ridge, where they cut both the Dripping Spring quartzite and the Globe limestone. One diabase dike cuts the quartz-porphyry mass on the Ray hill, the only one noted on the surface west of Mineral creek. There is also a body of diabase near the granite-porphyry across the creek, but the relation between the two is obscure. Within a mile below the bridge, at Ray, along the tramway, four diabase dikes are met. About a half mile lower occurs another dike several hundred feet thick. It is a tough finely crystalline, grayish-black rock, composed about equally of ferro-magnesian minerals and small feldspars. A thin section shows an intersertal texture, with no original pyroxene. This is altered to aggregates of hornblende and chlorite. The plagioclase is fairly fresh, while magnetite and some secondary quartz are sparingly present. Other dikes show coarser textures, and in some the intersertal texture is apparent megascopically. In the same distance two dikes of a different type occur. They are much altered, and have white opaque feldspars in a greenish-yellow ground-mass, similar to those described as diorite-porphyry in the Globe quadrangle.

The dacite flow and the Whitetail formation next demand attention. The flow of biotite-dacite, with the glassy variety of its base, is petrographically the most interesting rock in the district. The southern termination of the flow in this locality forms the capping of Teapot mountain, which appears as an isolated mass from the south, $2\frac{1}{2}$ miles northwest of Ray. To the north it covers a wide area. To the west of Devil's canyon branch of Mineral creek it is a much dissected area. On the eastern side of this branch the flow does not extend so far south. Four miles up the creek the rock forms both walls of the narrow canyon. The thickness of the flow on Teapot mountain is about 300 ft., which increases to the north. The lower glassy portion, which is here persistent, is 15 to 20 ft. thick. That the flow once extended farther south is shown by the remnants on the eastern side of Mineral creek. The most southerly one noted is halfway up the ridge, as far as the conglomerate pinnacle, one mile below Ray. Petrographically, the rock is uniform over a wide area, and is similar in all respects to that described farther north. It is a fresh, fine-grained, porphyritic rock, of pinkish-gray color, carrying fragments of other rocks. Abundant feldspars, fewer plates of biotite, and infrequent hornblende prisms are the noticeable phenocrysts. The average size is 1 to 3 mm., the latter size being rare. Quartz is insignificant as determined megascopically. Under the microscope the feldspar is seen to be plagioclase and the ground-mass glassy.

The lower part of the flow is largely a black glass of resinous lustre, with abundant clear glassy feldspars 1 mm. in length, a few reaching 7 mm. These are less fresh, and form a typical vitrophyric texture. The rock presents fine examples of wavy flowage-lines in the glass ground-mass. Underlying the remnants of the flow is a tuff resembling a felsitic rhyolite, having compact pink bands streaked with seams of white pumice. A thin section shows it to be composed of angular glassy fragments, with quartz and plagioclase in a ground-mass of glass. Below the dacite capping of Teapot mountain the lower part of the slopes consist of at least 300 ft. of stratified gravel and sand belonging to the Whitetail formation. It is also seen at the base of the dacite along Devil's canyon.

The Gila conglomerate is most prominent as a valley-deposit between Ray and Kelvin, along Mineral creek, but remnants occur on the eastern ridge above Ray. Commencing with a sharp pinnacle one mile below Ray, beds of this formation extend on both sides of Mineral creek as far as two miles above Kelvin. On the western side, $2\frac{1}{2}$ miles north of Kelvin, a steep cliff exposes a thickness of 200 ft. of horizontal sand and interbedded gravel from all the older formations. Some black basaltic knobs on the Florence plain are probably contemporaneous with the flow in the Globe quadrangle. In the vicinity of Ray none was observed.

The structure of the district is revealed by the examination of the greatly eroded area of stratified rocks on the west side of the granitic ridge at Ray. This ridge, with the schistose rocks of the Pinal for-

mation on its lower eastern side, has the aspect of a central nucleus, with sedimentary rocks resting unconformably on the eastern and western flanks. The eastern ridge from Ray south consists of a block of stratified rocks having a dip to the south. As seen from the summit of the ridge, this dip would carry it into the granitic area of the western ridge above Kelvin if it were not cut off by faulting. About 2½ miles north of Kelvin the dip changes to the east, and the trend of the ridge is up the Gila river, away from the granite. Opposite Ray the block terminates in rather steep cliffs marking a fault-line. The block is probably repeated in another to the north. From the slopes of the western ridge, a quarter mile below Ray, looking east to the opposite ridge, a fault can be noticed breaking the monoclinical dip of the Globe limestone beds on the summit, and another can be seen one mile south, with a fold in addition. The mass of the dacite flow extending from Teapot mountain four miles north to where it forms Devil's canyon is evidently faulted down to the north, as in this distance the base is cut by the creek, while at Teapot mountain it is at least 1500 ft. above it. Minor faulting, probably of different periods, as in the

Mineral Creek at Ray With Arizona Hercules Workings and the Eastern Ridge in Background.

Globe quadrangle, has taken place on the eastern ridge, resulting in dropping blocks of the Dripping Spring quartzite. One such fault can be seen along the tramway, three-fourths of a mile below Ray. Small masses of dacite are involved in the same movement, so that they have been dropped hundreds of feet below the capping of Teapot mountain, though part may be due to irregularities of the ground covered by the flow.

A few notes on the copper ores are appended, notwithstanding their incomplete character. In economic importance and geologic relations the deposits may be grouped into two classes. The first consists of bodies of oxidized ores closely related to the diabase dikes. It furnishes the noticeable surface indications of the presence of copper throughout the district. The first exploration work was done on these. There are three orebodies of important size which can be examined in open-cuts. The largest is that in the diabase dike at the Ray mine; the second is exposed on the Arizona Hercules property, and another, also in diabase, may be seen about a mile to the northeast. The ore in all of them occurs in irregular masses, with many narrow seams. In the mass at the Ray mine the ore-minerals are malachite, probably oxides, a little chalcocite, and small particles of metallic copper. The diabase of the Arizona Hercules orebody is perhaps better described as an

irregular mass than a dike. The ore from this working appears to be mostly green to black chrysocolla, in kernel-like structure, forming brittle masses. The black layers may be melaconite, or they may owe their color to manganese dioxide. In the third locality mentioned, the carbonate ore has a higher tenor than elsewhere. A trace of azurite is found here in thin seams in the malachite. The latter has been deposited as a cement in small remnants of the Gila conglomerate in some of the side gulches, being transported by the surface-waters, and it also stains patches of the brecciated quartzite along the creek. Cuprite was noticed in small masses in the Dripping Spring quartzite in the gulch at the north end of the area.

Of greater future importance is the deposit of low-grade sulphide, requiring concentration, which occurs at a comparatively shallow depth in the schistose rocks of the Pinal formation. The greatest underground development of this ore is at the Ray mine, where the shaft is 350 ft. deep. Mineralogically, the ore is simple, consisting of iron pyrite, possibly some chalcopyrite, and chalcocite disseminated in small particles through the rock, while pieces may be obtained showing veins of massive chalcocite one-half inch thick. That the chalcocite is of secondary origin is shown by the films of this mineral covering grains of pyrite, so that the percentage of copper is less than would be supposed on first inspection.

The exploration with churn-drills being carried on by the Ray Consolidated Copper Co. shows that there is a zone of oxidation above the main sulphide orebody in which carbonates and metallic copper occur, accompanied by much hematite. The copper is of secondary origin similar to that in the oxidized orebodies previously described. The limits of the orebody are generally found between the depths of 200 and 450 ft., and water is usually present at this depth. In some localities the last drillings contained pyrite only, indicating the lower limit of the zone of secondary sulphides. The relation of the surface of the orebody and the water-level to the overlying topography is an important subject yet to be worked out.

While the chalcocite is of secondary origin, a detailed study is required to determine the original source of the copper solutions and the wide dissemination of the primary sulphide. Masses of diabase and granitic rocks, with porphyritic variations, are liable to be found in any part of the area of Pinal schistose quartzite below the surface. Of these, the diabase intrusions, which are later in date than the others, are the most likely source of the copper, and the two types of deposit may have a common origin.

A bulletin has just been issued by the U. S. Geological Survey which discusses most of Esmeralda and Nye counties, Nevada, and Inyo county, California. It describes not only the region about Goldfield, but also Pahute mesa and the ranges near it, the Amargosa desert and mountain system, Death Valley, and the Panamint range. Besides gold, it discusses the water, vegetation, culture, and animal life of the region. It is accompanied by a geologic and topographic map. It is published for free distribution.

IRON ORE SUPPLY OF THE UNITED STATES.

By C. WILLARD HAYES.

*A chemical and geological classification of iron ores places the commercial deposits in six classes: (1) magmatic segregations in basic igneous rocks; (2) contact deposits formed in connection with igneous intrusions; (3) concentration deposits; (4) replacement deposits; (5) bedded deposits; and (6) gossan deposits. The iron ores are further distinguished under two classes: available and not available. This classification is in large measure arbitrary, and it is evident that it will vary from time to time. Actual production, past and present, being determined by the interaction of various factors, affords the best criterion of availability. For convenience, the known ore deposits are taken up by groups, based on distribution and kind. These groups are the following: 1. Lake Superior ores. 2. Adirondack ores. 3. Clinton ores. 4. Appalachian metamorphic ores. 5. Appalachian brown ores. 6. Appalachian carbonate ores. 7. West Tennessee brown ores. 8. East Texas brown ores. 9. Ozark ores. 10. Rocky Mountain metamorphic ores. 11. Igneous contact ores.

1. Lake Superior Ores.—The estimates of the Lake Superior ores are based upon the confidential records of practically all the mining companies of the region. The available ore under present conditions is taken to include all ore above 55% iron, and 25% of all ore between 45 and 55% iron. A recent compilation of diamond-drill samples indicates that the average content of iron in the iron formation, excluding the beds now considered ore, exceeds 37% of metallic iron. This may be regarded as constituting a low-grade ore not now available.

2. Adirondack Ores.—Estimates of the Adirondack ores are based upon information furnished by the New York State Survey. A certain portion of the titaniferous magnetites are included. This is on the assumption that either the percentage of titanium will be reduced by concentration methods, or the ores will be made available by modifications in furnace practice and the use of a special flux.

3. Clinton Ores.—The estimates of the New York Clinton ores are based upon information furnished by the New York Survey, and those in the Southern States chiefly upon information obtained by the United States Survey. Calcareous Clinton ores, carrying 30% metallic iron, are classed as available, provided they are so situated as to be economically mined. None of the silicious Clinton ores are considered at present available.

4. Appalachian Metamorphic Ores.—These ores include the deposits of magnetite and specular hematite, associated with crystalline and metamorphic rocks, of the Piedmont and Appalachian mountain belts, from southern New York to Alabama. Much uncertainty exists regarding the available tonnage in these deposits, and the estimates are correspondingly of low value.

5. Appalachian Brown Ores. This division in-

*Abstract of report prepared for the Conservation Commission and published in the Trans. Amer. Inst. Min. Eng.

TABLE I—ESTIMATES OF IRON-ORE SUPPLIES OF THE UNITED STATES, IN LONG TONS.

Commercial districts.	Magnetite ores.				Hematite ores.				Brown ores.				Carbonate ores.				Total supplies.	
	Non-titaniferous.		Titaniferous.		Specular and red.		Clinton.		A.		B.		A.		B.		A. Available.	B. Not available.

5. Rocky Mountain	151,485,000	4,275,000	2,100,000	2,000,000	1,625,000	57,760,000	120,665,000
6. Pacific Slope	468,950,000	10,000,000	105,000	68,950,000	23,905,000
Totals	292,935,000	4,761,740,000	90,000,000	128,500,000	3,529,275,000	67,552,100,000	508,540,000	1,620,500,000	367,400,000	743,230,000	310,000,000	4,788,150,000	75,116,070,000

1. Vermont, Massachusetts, Connecticut, New York, New Jersey, Pennsylvania, Maryland, Ohio. 2. Virginia, West Virginia, East Kentucky, North Carolina, South Carolina, Georgia, Alabama, East Tennessee. 3. Michigan, Minnesota, Wisconsin. 4. Northwest Alabama, West Tennessee, West Kentucky, Iowa, Missouri, Arkansas, East Texas. 5. Montana, Idaho, Wyoming, Colorado, Utah, Nevada, New Mexico, West Texas, Arizona. 6. Washington, Oregon, California.

¹Includes some hematite.

²Includes some titaniferous magnetite.

cludes those deposits of limonite and other hydrous oxides which occur associated with the closely folded belt of sedimentary rocks from Pennsylvania southward to Alabama. Of these, the Oriskany ores are most readily estimated, while the ordinary concentration deposits of brown ores associated with other formations cannot be estimated with any degree of accuracy. The estimates of competent experts differ from the figures given in this paper by factors varying from 0.7 to 3.

6. Appalachian Carbonate Ores.—This division includes the thin beds of ore associated with the Carboniferous rocks of western Pennsylvania, eastern Ohio, and Kentucky, formerly an important source of iron, but now practically unworked. All of these ores are placed in the not-available class.

7. West Tennessee Brown Ores; 8. East Texas Brown Ores; and 9. Ozark Ores.—From the nature of distribution and occurrence, estimates of the tonnage of ores in these districts in the lower Mississippi Valley are very uncertain.

10. Rocky Mountain Metamorphic Ores.—This group embraces deposits of magnetite and specular hematite associated with crystalline schists and gneisses at various localities in the Rocky Mountain region. Except the deposits in the Hartville district, Wyoming, very little is known concerning their distribution or tonnage.

11. Igneous Contact Ores.—This group is based exclusively upon geologic relations, and includes widely separated deposits, the principal ones in the East being the Cornwall type of eastern Pennsylvania. Most of them are situated in the Rocky Mountain and Pacific States. Some of these deposits are fairly well known, but concerning others only the roughest sort of an estimate is available.

I have considered very briefly the supplies of foreign iron ores so situated that they will probably enter into the iron industry of the United States in the future (see Table II). These are the Canadian and Newfoundland ores and Cuban ores. None of these countries has an abundant fuel supply, and therefore either the fuel must be imported or the ore exported. The history of the iron industry indicates that the latter is more likely to occur, particularly since the industry is already established, and the chief market for the finished product is near the fuel supply.

TABLE II—ESTIMATED AVAILABLE FOREIGN IRON ORE, IN LONG TONS.

Canada:	
British Columbia, magnetite chiefly.....	30,000,000
Lake Superior district, hematite chiefly...	9,000,000
Nova Scotia, Clinton hematite	4,000,000
Newfoundland, Clinton hematite	30,000,000
Mexico, magnetite and brown ore
Cuba:	
Santiago district, hematite	5,000,000
Mayari, Moa, Baracoa, Cubitas, and Pinar del Rio districts (limonite).....	1,500,000,000
	1,578,000,000
Imports and exports of iron ore, in long tons.	
Total imports, 1889-1907.....	14,705,842
Total exports, 1889-1907	1,271,214

The production of iron ores by commercial districts in 1906 and 1907 is given in Table III.

TABLE III—PRODUCTION OF IRON ORES IN THE UNITED STATES IN 1906 AND 1907.

District.	1906.		1907.	
	Long tons.	Total. %.	Long tons.	Total. %.
Northeastern	2,582,666	5.40	2,822,822	5.45
Southeastern	6,208,140	13.00	6,197,360	12.00
Lake Superior	38,035,084	79.66	41,638,744	80.50
Mississippi Valley	117,570	0.25	230,435	0.46
Rocky Mountain*	806,268	1.70	831,258	1.60
Total	47,749,728	100.00	51,720,619	100.00

*The small production of California and Washington is included in the production of the Rocky Mountain district.

The data in Table III indicate the commanding position of the Lake Superior district in the iron industry, with 79.66 and 80.50% of the total production for the years 1906 and 1907.

The production of iron ore in the United States by decades, from 1870 to 1909, is given in Table IV.

TABLE IV—PRODUCTION OF IRON ORE IN THE UNITED STATES BY DECADES, 1870 TO 1909.

Decade.	Production, long tons.	Increase, %.
1870-1879	43,770,527
1880-1889	91,043,854	108.0
1890-1899	163,989,193	80.1
1900-1909	about 392,000,000	138.0

Each of the decades given in Table IV, if shown by a production-curve, would contain a depression in which there was an actual decrease in production, so that they may be taken as fairly representing the tendency of the industry. These rates of increase are such that they do not permit the construction of a curve on which predictions for the future can be based. A comparison of the first and second rates, 108 and 80.1, would indicate a rapid decrease in the rate of increase, which if continued would have placed the date of maximum production at about 1930. But a comparison of the second and third rates, 80.1 and 138, would indicate a rapid increase in the rate of increase. If the average rate of increase by decades, 108%, should be continued, it would require the production in the next three decades of 6,088,000,000 tons. But the ore supply now available in the United States is estimated at 4,786,000,000 tons, which is only 78% of the amount needed on this assumption. It is evident, therefore, that the present average rate of increase in production of high-grade ores cannot continue even for the next 30 years, and that before 1940 the production must have already reached a maximum and begun to decline, and a very large use must be made of low-grade ores not now classed as available. The second condition, with its consequent greatly increased cost of iron, is the only thing which can prevent a decline in the iron industry, measured by the amount of pig-iron produced, within the next 30 years, unless there is in the meantime very greatly increased importation of foreign ores.

In view of the many factors entering into the problem, the tendency of which is not always determinable, to say nothing of the weight that should be given them, any further prediction as to the date of exhaustion of the iron-ore supplies is so uncertain as to be wholly unprofitable and unwarranted.

COMPANY REPORTS.

WAIHI GOLD MINING CO., LTD.

The report for 1908 on the famous New Zealand gold mine shows that during the year 393,214 tons of ore were treated. The gold and silver realized amounted to £930,511 7s. 6d., which, with £9023 2s. 5d. from interest, gave a total revenue of £939,534 9s. 11d. The profit for the year was £558,141 10s. 9d., which was an increase of £27,230 17s. 7d. over that for 1907. Regular dividends for the year amounted to £371,930 5s. This, with the bonus of £49,500 14s. recommended, this is equivalent to 17s. per share for the year. The ore reserves on December 31 were estimated at 1,329,872 short tons, as compared with 1,299,979 at the corresponding period the year before. Development during the year was satisfactory. In order to provide power for a larger pumping plant, two 750-hp. Crossley gas-producers and two 368-hp. gas-engines, with two electrically driven three-throw ram pumps, have been ordered. A new steel head-frame has been erected at shaft No. 4. The total number of stamps running was 315 out of 330. The average stamp duty was 4.17, a slight increase. The extraction at the Waihi mill, according to assay, was 89.3% of the gold and 75.8% of the silver. At the Victoria mill the corresponding figures were 91.2 and 72.3, and at the Union mill, 88.4 and 69.5. The concentrate was treated at the Victoria mill with a saving of 96.28% of the gold and 92.95 of the silver. At the acid treatment plant 1,591,674 oz. of doré, valued at £898,775 16s. 1d., were treated.

STANDARD CONSOLIDATED.

This company, whose mines near Bodie, California, have produced bullion to a total value of \$15,406,176, paid in 1908 a dividend of \$35,678, making a total of \$4,294,130 since the consolidation in 1879. Adding to this the \$900,000 prior dividends, a total of \$5,194,130 in profits stands to the credit of the property. Recently the company had not done well, and a new management was installed for 1908. Within the year substantial progress was made in reorganizing the business of the company and putting both mine and mill in shape. W. H. Landers, superintendent, presents a report replete with detail. The ore reserves are stated to amount to 4380 tons. Within the year 3282 ft. of development were driven, at a total expense of \$18,687. This produced 2047 tons. The high cost is explained by the price of labor and the small size of the veins, which vary in width from 1 to 4 in., and show little cleavage between vein and wall. Owing to a strike, active operations were confined to 10 months. In that time 14,229 tons were extracted and milled, a duty of 2.8 tons per stamp per day. The average value of the ore per ton was \$16.36; of the tailing which goes to the slime plant, \$6.08; and of the tailing from the latter, \$1.13. The total indicated extraction was 90%, and the actual 87.92. An interesting feature of the report is a table showing the actual amount of work done on each vein, its cost for labor, and the amount of ore developed. The extremely variable cost of ore is well shown.

ESPERANZA, LTD.

The Esperanza, Ltd., is an English company owning 449,800 out of a total of 450,000 shares of the Esperanza Mining Co., operating mines at El Oro, Mexico. In 1908 dividends to the amount of £307,136 3s. 5d. were paid, and at the end of the year the liquid assets were £172,997. According to Cortlandt E. Palmer, consulting engineer, the total production of this property has amounted to £49,114,860. In 1908, 145,451 metric tons, having a value of \$2,146,290, were produced, at a profit of \$927,616. Development amounting to 9513 ft. was accomplished, and was satisfactory on both the San Rafael vein and in the sulphide veins in the north end of the property. The ore reserves are estimated at 238,034 dry metric tons, capable of yielding a net profit of \$2,177,222. The gross value per ton of output in 1908 was \$14.75, as compared with \$20.63 in 1907. Operating expenses were reduced 17% within the year, and amounted to \$7.25 per ton, of which amount \$5.87 was the cost of mining and milling, \$0.74 selling and \$0.64 general administration. The report is accompanied by detailed maps and plans of the property.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

CONSTRUCTION OF EXPLORATION CONTRACT.

A contract by a land-owner with a prospector, giving him the exclusive right to explore certain lands for mineral substances, and by which the explorer agreed, in case of success, to pay the owner \$100 per acre for the land within 90 days after any valuable discovery, the explorer was not bound to drill to find commercial substances or minerals, but was only required to purchase the land at the specified price in case of such discovery of commercial substances. And the finding of oil in less than paying quantities, and the finding of a stratum of salt several hundred feet below the surface, was not a success in finding commercial substances, within the meaning of the contract.

Anse La Butte Oil & Mineral Co. v. Babb, (La.) 47 South. 754. Dec. '08.

CONSTRUCTION OF COAL LEASE.

A coal lease provided that the lessee should pay a certain price for all coal that would pass over a screen of an eighth of an inch mesh, and that all that passed through should be classed as culm, and in case of sale of such culm, the lessee should pay one-tenth of the net profit to the lessor. In an action to recover the lessor's part of the profit on the culm, it was decided to be a question for the jury whether the entire cost for mining coal and culm was to be considered, or whether it was impossible for the lessee to prepare the royalty coal for market without producing culm, and that when sold the entire price, less the cost of loading such culm, was the net profit.

Woodruff v. Gundon, (Pa.) 71 Atl. 849. Jan. '09.

MINING CONTRACT—NATURE AND CONSTRUCTION.

A contract in consideration of one dollar and of a royalty, granted to the obligee all the bituminous rock and other minerals he might choose to mine, quarry, and take from certain lands; it further provided that in case the lands failed to produce minerals in paying quantities or of good quality, the obligee might, upon 30 days' notice in writing to the obligor, relinquish his rights, and that the obligee should pay royalty on 300 tons annually, whether taken or not. In the performance of the contract the obligee quarried and took away 27 tons of rock, and conducted no further operations to the time of his death, 15 years later, though he paid royalty for two years. In an action between the obligor and the heirs of the obligee, it was decided that the contract was not a grant of land nor a lease, but was a grant of a right only, and that all the rights of the obligee, and consequently of his heirs, were extinguished by the voluntary abandonment of the right, and that the obligor waived the 30 days' written notice required.

Payne v. Neuval, (Cal.) 99 Pac. 476. Jan. '09.

CONSTRUCTION OF OIL LEASE.

Land owners granted to a lessee the exclusive right to enter on certain lands, to drill wells, mine, and to do all that was necessary and proper for the development and extraction of oil, etc., with the privilege of passing over such lands and of maintaining necessary structures thereon for the objects of the lease; to hold the premises for 20 years, unless otherwise terminated, the lessee to have the right to abandon the lease at any time that it was deemed unprofitable to operate; the lessee to pay a stipulated royalty for all oil produced. Such a lease was held to vest no present title in the lessee to stratum of the land in place, but left the title to the oil in the land owner until it was brought to the surface, vesting in such lessee an estate for years for the purpose of taking oil therefrom, giving the lessee the right to extract and remove the oil from the premises, and which constituted for the time a servitude on the land.

Graciosa Oil Co. v. Santa Barbara County, (Cal.) 99 Pac. 483. Jan. '09.

Permissible Explosives.

*As a part of the investigation of mine explosions authorized by Congress in May 1908, it was decided by the Secretary of the Interior that a careful examination should be made of the various explosives used in mining operations, with a view to determining the extent to which the use of such explosives might be responsible for the occurrence of these disasters. The preliminary investigation showed the necessity of subjecting to rigid tests all explosives intended for use in mines where either gas or dry inflammable dust is present in quantity or under conditions which are indicative of danger. With this in view, a letter was sent by the Director of the United States Geological Survey on January 9, 1909, to the manufacturers of explosives in the United States, setting forth the conditions under which these explosives would be examined, and the nature of the tests to which they would be subjected.

Inasmuch as the conditions and tests described in this letter were subsequently followed in testing the explosives given in the list below, they are here reproduced, as follows: (1) The manufacturer is to furnish 100 lb. of each explosive which he desires to have tested; he is to be responsible for the care, handling, and delivery of this material at the testing station on the United States Arsenal grounds, Fortieth and Butler streets, Pittsburg, Pa., at the time the explosive is to be tested; and he is to have a representative present during the tests, who will be responsible for the handling of the packages containing the explosives until they are opened for testing. (2) No one is to be present at or to participate in these tests except the necessary Government officers at the testing station, their assistants, and the representative of the manufacturer of the explosives to be tested. (3) The tests will be made in the order of the receipt of the applications for them, provided the necessary quantity of the explosive is delivered at the plant by the time assigned, of which due notice will be given by the Geological Survey. (4) Preference will be given to the testing of explosives that are now being manufactured and that are in that sense already on the market. No test will be made of any new explosive which is not now being manufactured and marketed, until all explosives now on the market that may be offered for testing have been tested. (5) A list of the explosives which pass certain requirements satisfactorily will be furnished to the State mine inspectors, and will be made public in such further manner as may be considered desirable.

The tests will be made by the engineers of the United States Explosives Testing Station at Pittsburg, Pa., in gas and dust gallery No. 1. The charge of explosive to be fired in tests 1, 2, and 3 shall be equal in disruptive power to one-half pound (227 grams) of 40% nitroglycerine dynamite in its original wrapper, of the following formula:

	%.
Nitroglycerine	40
Nitrate of sodium	44
Wood pulp	15
Calcium carbonate	1

100

Each charge shall be fired with an electric fuse of sufficient power to completely detonate or explode the charge, as recommended by the manufacturer. The explosive must be in such condition that the chemical and physical tests do not show any unfavorable results. The explosives in which the charge used is less than 100 grams (0.22 lb.) will be weighed in tinfoil without the original wrapper.

The dust used in tests 2, 3, and 4 will be of the same degree of fineness and taken from one mine.¹

Test 1.—Ten shots with the charge as described above, in its original wrapper, shall be fired, each with 1 lb. of clay tamping, at a gallery temperature of 77° F., into a mixture of gas and air containing 8% of methane and ethane. An

explosive will pass this test if all ten shots fail to ignite the mixture.

Test 2.—Ten shots with charge as previously noted, in its original wrapper, shall be fired, each with 1 lb. of clay tamping at a gallery temperature of 77° F., into a mixture of gas and air containing 4% of methane and ethane and 20 lb. of bituminous coal dust, 18 lb. of which is to be placed on shelves laterally arranged along the first 20 ft. of the gallery, and 2 lb. to be placed near the inlet of the mixing system in such a manner that all or part of it will be suspended in the first division of the gallery. An explosive will pass this test if all ten shots fail to ignite the mixture.

Test 3.—Ten shots with charge as previously noted, in its original wrapper, shall be fired, each with 1 lb. of clay tamping at a gallery temperature of 77° F., into 40 lb. of bituminous coal dust, 20 lb. of which is to be distributed uniformly on a horse placed in front of the cannon and 20 lb. placed on side shelves in sections 4, 5, and 6. An explosive will pass this test if all ten shots fail to ignite the mixture.

Test 4.—A limit charge will be determined within 25 grams by firing charges in their original wrappers, untamped, at a gallery temperature of 77° F., into a mixture of gas and air containing 4% of methane and ethane and 20 lb. of bituminous coal dust, to be arranged in the same manner as in test 2. This limit charge is to be repeated five times under the same conditions before being established.

Note.—At least 2 lb. of clay tamping will be used with slow-burning explosives.

In response to the above communication applications were received from 12 manufacturers for the testing of 29 explosives. Of these explosives, the 17 given in the following list have passed all the test requirements set forth, and will be termed permissible explosives:

Brand.	Manufacturer.
Aetna coal powder A.	Aetna Powder Co., Chicago, Ill.
Aetna coal powder B.	Do.
Carbonite No. 1.....	E. I. Du Pont de Nemours Powder Co., Wilmington, Del.

Meteor dynamite	E. I. Du Pont de Nemours Powder Co., Wilmington, Del.
Monobel	Do.

Subject to the conditions named below, a permissible explosive is defined as an explosive which has passed gas and dust gallery tests No. 1, 2, and 3 as described above, and of which in test No. 4 1½ lb. (680 grams) of the explosive has been fired into the mixture there described without causing an ignition. Provided: (1) That the explosive is in all respects similar to the sample submitted by the manufacturer for test. (2) That double-strength detonators are used of not less strength than 1 gram charge consisting by weight of 90 parts of mercury fulminate and 10 parts of potassium chlorate (or its equivalent), except for the explosive 'Masurite M. L. F.', for which the detonator shall be of not less strength than 1½ grams charge. (3) That the explosive, if in a frozen condition, shall be thoroughly thawed in a safe and suitable manner before use. (4) That the amount used in practice does not exceed 1½ lb. (680 grams) properly tamped.

It may be wise to point out in this connection certain differences between the permissible explosives as a class and the black powders now so generally used in coal mining, as follows: (a) With equal quantities of each, the flame of the black powder is more than 3 times as long and has a duration 3000 to more than 4000 times that of one of the permissible explosives; also the rate of explosion is slower. (b) The permissible explosives are 1¼ to 1¾ times as strong, and are said, if properly used, to do twice the work of black powder in bringing down coal; hence only half the quantity need be used. (c) With 1 lb. of a permissible ex-

¹Explosives Circular No. 1, U. S. Geological Survey.
²With a view to obtaining a dust of uniform purity and inflammability.

plosive or 2 lb. of black powder, the quantity of noxious gases given off from a shot averages approximately the same, the quantity from the black powder being less than from some of the permissible explosives and slightly greater than from others. The time elapsing after firing before the miner returns to the working face or fires another shot should not be less for permissible explosives than for black powder.

The use of permissible explosives should be considered as supplemental to and not as a substitute for other safety precautions in mines where gas or inflammable coal dust is present under conditions indicative of danger. As stated above, they should be used with strong detonators; and the charge used in practice should not exceed $1\frac{1}{2}$, and in many cases need not exceed 1 lb. Inasmuch as no explosive manufactured for use in mining is flameless, and as no such explosive is entirely safe under all the variable mining conditions, the use of the terms 'flameless' and 'safety' as applied to explosives is likely to be misunderstood, may endanger human life, and should be discouraged.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE COPPER HANDBOOK: A MANUAL OF THE COPPER INDUSTRY OF THE WORLD. Compiled and published by Horace J. Stevens. Vol. VIII, pp. 1500, index. Houghton, Mich., 1908. Price \$5.

This indispensable guide to the activities of the copper world for the year 1908 has just been issued, with 272 pages in excess of the number contained in the preceding volume. The increase has been due almost entirely to the need of room for details of new companies, which shows a substantial growth, despite hard times. The work of compiling has been done with that scrupulous care which has distinguished the previous work of Mr. Stevens—work which has made 'The Copper Handbook' recognized as a reliable guide to the subject, rather than a mere compilation of self-praise submitted by weak companies and sparse data relating to important concerns, after the habit of some other company directories. Mr. Stevens has assumed the critical attitude of the editor, seeking and publishing information with due regard to the importance of the operations recounted, and fearlessly exposing fraud and mismanagement. It thus becomes a responsible publication, with statements the accuracy of which it is prepared that the courts shall test. It sometimes results in spicy paragraphs, as for example where it scores both the Government and Douglas, Lacey & Co. (p. 638), in the following terms:

"Efforts, begun November 1903, to have the methods of this firm investigated by the United States Postal Department, have come to naught, although the matter was pushed persistently, and finally was taken to the President of the United States, and by him referred back to one George Bruce Cortelyou, then Postmaster-General, and later Secretary of the Treasury of the United States, who 'investigated' the firm by advising them privately of the charges against them, and accepted their answer, which was that 'The Copper Handbook' is a blackmailing publication, this answer being perfectly satisfactory to the Hon. Mr. Cortelyou, best known as the gentleman who 'fried the fat' out of sundry insurance companies and other corporations, for the presidential campaign of 1904."

Thos. W. Lawson's operations at Trinity are characterized as a "scientific little game for parting fools from their money," with more of like uncomplimentary flavor. The wild-cats are mercilessly scored throughout, and any prospective investor in copper stocks who does not take the trouble to look up the record of the alluring company in 'The Copper Handbook' is rushing on in wilful blindness. There is one suggestion we would make for future editions, namely, a geographical index of mines, so that a person purposing to visit any particular State or county might have a guide to all the properties in that locality.

MILLWRIGHTING. By James F. Hobart. 8vo., pp. 401, Ill., index. Hill Publishing Co., New York. 1909. Price \$3.

The millwright is not a book-made man; his skill is the result of knowledge acquired in practice; his is a trade. Hence any millwright will know more than any other millwright will put into a book. But no two men's information is compressed within the same dimensions, and Mr. Hobart has given much that will help his brethren. He has done his work well, and we commend especially the chapters on Laying Out Shafting, Putting Pulleys in Place, Belts and Belting, and Steam and Water Pipe Fitting. The discussion of foundations, erection of structures, and strength of materials is too superficial to yield more than an occasional practical hint.

INVESTIGATIONS RELATING TO CEMENT AND CONCRETE MATERIALS. By G. C. Martin, L. J. Pepperberg, and Charles Butts. U. S. Geol. Surv., Bull. 380-J, pp. 34. Washington, 1909.

INVESTIGATIONS RELATING TO BUILDING STONES. By Sidney Paige. U. S. Geol. Surv., Bull. 380-I, pp. 17. Washington, 1909.

INTERNATIONAL MINING MANUAL. Advance sheets. Alaska to Colorado. From the Directory for 1909.

BELLE FOURCHE FOLIO (S. Dak.). U. S. Geological Survey, Washington. 1909.

Electric Mining Locomotive for Japan.

The Baldwin Locomotive Works have recently built three electric mining locomotives for the Ishikari Coal Co., of Japan. These are compact machines, designed for a track gauge of 1 ft. 8 in. The approximate weight is 6000 lb. The electrical equipment was supplied by the Westinghouse

Electric & Manufacturing Co. The frames of the locomotives are of steel plates, strongly reinforced by angle irons, which are riveted on. The pedestals are of cast-iron. The frames are placed outside the wheels, and the weight is transferred to the journal boxes through coiled springs. The wheel base is 3 ft. 6 in., and the wheels are 20 in. diam., with $2\frac{3}{4}$ by 4 in. journals. The motors are classed as No. 64; they are wound for 500 volts pressure, and are inside hung. The trolley pole socket is placed on the centre line of the locomotive, near the front end. The clearance dimensions are as follows: width, 2 ft. $11\frac{1}{8}$ in.; height, 3 ft. $5\frac{1}{2}$ in.; length, 8 ft. 9 in. The equipment includes hand brakes, sand boxes with spouts for all the wheels, and two electric headlights. The locomotive is operated from one end only, and due attention has been paid to arranging the fittings so that it can be conveniently handled.

L. VOGELSTEIN & Co., of New York, give the following figures of German consumption of foreign copper for the months January to March, 1909:

	Tons.
Imports of copper.....	36,105
Exports of copper.....	2,075
Consumption of copper.....	34,030

Of the above quantity, 33,291 tons were imported from the United States. Consumption during the same period in 1908 was 42,830 tons.

EDITORIAL.

CONGRESS is tediously laboring to reduce the tariff without interfering with the joy of the trusts.

WATER has been turned into the Yukon ditch, and the reward of careful planning and much hard work is at hand. Our congratulations to Mr. O. B. Perry and his fellow engineers.

SALISBURY WASH is the latest centre of enthusiasm in Nevada. Reports of extraordinary discoveries of silver-gold ore are drawing hordes of excited fortune-hunters. The new camp lies about thirty miles east of Tonopah and is seven miles from Clifford. It has just been re-christened Ellendale.

IBERIA has no further attractions for Mr. Jafet Lindeberg, who has given up his contest with the Russian Government over seizure of his claims in the Anardirf country. This is unfortunate, as Mr. Lindeberg is an able man, of the type that could aid most in developing our neighbor's great resources. Before passing harsh judgment on the Russians, however, it would be well to remember that at Nome the Americans have no very enviable record for giving exact and prompt justice.

WAR kills off the able and leaves the drones behind; the inheritance of war is therefore decadence. So teaches a certain school of disarmament enthusiasts. The argument is alluring; it hits the whole race; for we are all descendants from the lucky survivors of incorrigible fighters. It therefore becomes invidious to single out a particular nation for uncomplimentary mention, as did Dr. David Starr Jordan in a recent Commencement address. There was an offended French professor on the platform, and a hitch in the proceedings, which either wit, tact, or courtesy, might have averted. Debate as to the facts might have been interesting; someone could have suggested the marvelous leadership in metallurgy which the French have recently displayed, to go no farther afield; and another, remembering a book on evolution which the learned Doctor has just published, could have made pertinent query why the cultivation of a propensity, even for war, may not develop the heroic faculties. Who knows?

ALASKA has a new Governor, Mr. W. A. Clark. The selection of a newspaper man for this position has much to recommend it. Our 'non-contiguous continental possession' is governed by a peculiar system, having judicial and executive but no legislative department. Practically the Federal Judges are the ruling powers, and Mr. Edward E. Cushman, who took the oath as Judge of the Third Division of

the Federal Court of Alaska at Tacoma June 6, will have more actual power than Mr. Clark. The duties of the Governor of Alaska are varied. Perhaps his most important function is to make recommendations to the Washington Government. The force of these depends on his character and standing, and the care with which he has studied the situation. We are glad to assure our Alaskan friends that Mr. Clark has, among his associates, a high reputation for character and ability. As a trained newspaper writer, familiar with affairs at Washington, he should be peculiarly able to determine the drift of local opinion regarding the needs of the Territory, and to command the support necessary to the adoption of his recommendations. Alaska has been often shabbily treated at Washington, but we hope better times are in store.

ARRREST is a needlessly harsh measure for enforcing the collection of taxes. The indictment for conspiracy of the officers of the Pittsburg Silver Peak and the Florence Goldfield companies in Nevada, as detailed in our special correspondence, savors of comic opera. The bullion tax is a personal one, assessed on net returns. That there is abundant room for honest difference of opinion as to what are legitimate charges and what constitute net returns, is clear to anyone who has tried fairly to distribute charges between operating and capital accounts. We do not know the details in this case, but Mr. Edmund Juessen and others mentioned are not the sort that indulge in dishonest practice. If the particular division of accounts adopted by the companies concerned is not correct, the easy remedy is a civil suit to recover. In this case there is abundant tangible property to make such a suit worth while. Tax laws are enacted to produce revenue. If mining engineers are to be arrested whenever their ideas of bookkeeping fail to agree with those of the local grand jury, their life bids fair to be more exciting, if not so attractive.

SLIME is one of the least comprehended products with which the millman has to deal. It has baffled him persistently. Yielding neither high recovery of minerals in concentration, nor of metals by lixiviation, it has remained a constant cause of loss; yet the problem has not been approached in a scientific manner by metallurgists. Attempts to control slime have been made empirically, and the successes achieved have mostly been lucky accidents. The nature of the material has not been sufficiently investigated. The clay-workers, meanwhile, have been probing the mysteries of similar complex substances which they call 'slips', and this week we print a remarkable article from the pen of Mr. Harrison Everett Ashley which will afford a glimpse into a new field of research for the producers of gold and silver. The clear statement of the reason why lime as a settling agent has been so puzzlingly erratic, will attract wide attention. Mr. Ashley might have drawn further from his acquaintance with this matter and have told how our methods of grinding increase the colloids in ore-pulp, opposing the most serious of obstacles to high extraction. The article, in fact, is only a brief introduction to a subject on

which data have already been accumulated that will mean millions of dollars annually to the precious metal miners when applied to their milling processes.

ACCIDENTS in mines are inevitable. The most abundant precautions and most stringent rules merely serve to reduce the number. The burden of caring for the injured is not removed. In order to make each industry sustain its own obligations, counting such items as part of the cost of production, an effort is now being made by a tonnage tax, to provide for those maimed, and to care for the widows and orphans of those killed in coal mines. The need of some protection in these mines is especially urgent because of the high accident rate and low yearly wage, though doubtless success here will lead to similar demands in other mines. The equity and the economy of the move are more apparent than the legal means of effecting the change. The American Mining Congress has taken the lead by appointing an able committee to prepare a suitable statute for presentation to the State legislatures. In view of the close competition between the coalfields of the various States, immediate results can hardly be anticipated. The resulting agitation of the question will at least focus attention on an important problem.

Moisture in Coke.

Coke is now being purchased on the basis of net dry weight by the smelters on the Pacific Coast. This has aroused much opposition from foreign shippers. Australian coke is usually low in moisture, but the European contains generally about eight per cent. The smelters allow three per cent without deduction from the gross weight of the coke. The determination is made upon fifteen-pound samples crushed to a half inch, dried in a steam-heated dessicator at a temperature of 240 degrees Fahrenheit. The samples are said to check within less than two-tenths of one per cent, which appears remarkable. It would seem that the rate of re-absorption on cooling would vary within wide limits, depending upon the relative friability of the coke. Also the moisture in the air would ordinarily differ enough to preclude agreement with an umpire, unless the samples were tested at the same time and place under identical conditions. It seems manifestly unfair to charge for material not delivered, but this is only one phase of the problem involved in reaching a fair valuation of a fuel. When attempting to sell fuels on a scientific basis a host of difficulties arise. The method of determining the objectional constituent is open to scrutiny. If the moisture be absorbed prior to shipment the consumer must inevitably, in one way or another, pay the freight. Once the game of deductions, or penalizing, has been fairly inaugurated, technologic finesse will discover additional points of vulnerability in the coke-maker's armor. Not only is moisture not carbon, but it consumes carbon to expel it; the coke-manufacturer therefore must submit to a lopping off at each end to arrive at the net weight. It were to inquire too curiously, perhaps, to consider the loss from oxidation facilitated by the absorption of moisture.

Seriously, the move is in the right direction. The purchase of net dry coke will soon become universal. Why an allowance of any percentage of moisture should be made we do not see. The restriction as to quality will necessarily be met by a corresponding increase in the price on the net-weight paid for, for manifestly the freight on the water must be paid by someone. Coke will take up water in proportion to the relative dryness of the air, and drying of the coke prior to shipment would be of no avail.

Opportunities in Asia Minor.

Under the new régime progress may be anticipated in Turkey, and a great area in Asia Minor will be available for development. Within this region lay ancient Cappadocia, where the copper industry as a nursling in the early days of Indo-European man yielded bronzes that inaugurated a new era in human culture. The copper resources of that district are known only in a general way, but the indications point to extensive deposits. It is a region of wild mountains inhabited by tribes which have repelled the advances of strangers. Gold, lead, silver, mercury, coal, and iron abound. The Arghana mine is one of the oldest in the world that has been continuously worked. It was opened in the year 1096 A.D., and was described as a famous producer of silver by Omar the Traveler at the beginning of the twelfth century. This does not, of course, go so far back as the Laurium mines of Greece, which reckon their age by milleniums, nor does it equal the antiquity of the Rio Tinto in Spain, which still gives a controlling power in the copper market to the English corporation that owns it. Freiberg and Przibram also claim great age, but eight centuries of continuous operation under the barbarous conditions which have had to be combatted in Asia Minor proves the existence of a deposit of remarkable character, one that incites the miner to hope for many others which will prove amenable to modern methods. It is unquestionable that the new ruler of Turkey, coming to the throne pledged to reform, will infuse a progressive spirit throughout his dominions. It is therefore to be expected that liberal laws will invite the unfolding of the mineral deposits which have remained dormant for centuries. In so far as possibilities of exploitation by twentieth century methods are concerned, it is a virgin field. The article on 'Mineral Resources of the Turkish Empire', by Mr. Leon Dominian, published in this issue, will be of great value to that growing number of investors for whom no corner of the world is too far away if profit be in sight. Asia Minor is becoming readily accessible through railroad construction. The Anatolian line, under German management, starting from Constantinople, strikes across the upper peninsula to Aintab, where it divides, one branch continuing across the desert toward Bagdad, which city is now nearly reached by the rails; the other branch swinging through a series of wadys behind the coast range which parallels the Mediterranean, to Mecca. Asia Minor is a land of remarkable opportunity, and he who has courage to enter early should reap proportionate benefit.

American Securities Abroad.

That France takes banker's toll from the world has become appreciated by our people during the recent financial stress; that France has stood financially sound while tremors passed through every other great industrial nation in the world has been an impressive spectacle of the last two years. One is reminded by it of the unlimited resourcefulness of the French which so astounded Bismarck. Having by superior military power forced his way to the Tuileries, he sought to crush the country under the load of a preposterous war indemnity, aggregating nearly four billion dollars, but within a few short years the sum was paid, and France has continued financially impregnable. She effects exchange for the whole of Europe; like a great lake the financial streams of the Continent flow into and out of France; the floods are equalized, and the great fluctuations, so characteristic of American securities, are not seen abroad. Stocks and bonds, once listed on the Paris Bourse, are known to have been severely scrutinized. Behind them exist substantial assets and demonstrable earning power. Dependableness is the quality demanded by the managers of the Bourse. In America the speculative feature has dominated the financial and industrial system; hence the wild flight of prices, the upward sweep from sudden enthusiasm, and the collapse after the manipulators unload upon the credulous public. Capitalization here is usually based upon highly speculative estimates of value and profit. Hence not a single American security had ever been accepted on the Paris exchange until Mr. J. P. Morgan the other day, through Morgan, Harjes & Company, listed one million shares of the United States Steel common stock on the Bourse. This is one of the most notable events in our financial development, and will have a far-reaching influence. A new standard of stability will be set for our industrials. The further this listing proceeds, the narrower will become the range of general quotations. Steel common has been rising rapidly. A month ago it was 54; at the end of May it stood at 59, the highest on record up to that time; since then it has mounted to 69, steadying a little within the week. This has been due partly to the prospective increase of income from the forty-nine million dollars expended out of surplus in constructing the Gary plant, and partly to the effect of the new Continental market opened through the generalship of Mr. Morgan. It is believed that one purpose of Mr. E. H. Harriman's visit to France is the listing of the stock of the Southern Pacific on the Bourse. With the retirement of the preferred shares, and the large increase in earnings, it would seem to be acceptable. This new phase in American stock transactions will benefit our industrial enterprises in general, and will open new investments to Europe. Perhaps nothing could have happened that would so surely cause a business revival. In view of the influx of foreign capital resulting from the purchase of American securities abroad, great activity may be confidently predicted to follow immediately. Possibly the recent energy displayed by those controlling the copper industry was promoted by anticipation of such European aid.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. W. HARDINGE was in San Francisco.

PERCY E. BARBOUR has gone to Salt Lake.

FRANK W. OLDFIELD has been in San Francisco.

JAS. M. HYDE is living at Palo Alto, California.

H. S. DENNY is in the Black Hills, South Dakota.

C. S. HERZIG is at the Babilonia mine, La Libertad, Nicaragua.

L. I. OGDEN is inspecting State work at San Jose, California.

V. FRANK TAYLOR is returning to London from South Africa.

G. S. CORSTORPHINE has returned to South Africa from London.

J. W. FINCH, of Denver, has gone to Butte, Mont., and Wallace, Idaho.

H. C. WILMOT has opened an office in the Newhouse building, Salt Lake, Utah.

ARTHUR C. FOX is superintendent for the Duluth-Pacific Copper Co., at Clealum, Washington.

E. J. CLARK has resigned the position of superintendent of La Palmilla mine, Parral, Mexico.

ROBERT SCHORR has moved his office from 61 Fremont street to the Postal Telegraph building.

JAMES BROWN, representing the Tharsis Sulphur & Copper Co., Ltd., was in San Francisco this week.

L. A. WOMBLE is general manager for the Van Dyk Proprietary Mines, Ltd., Boksburg, Transvaal.

W. PELLEW HARVEY has returned to London after professional visits to New South Wales and to Northern India.

J. A. GRENFELL, chairman of the directors of the Messina (Transvaal) Development Co., Ltd., is visiting the Rand.

WM. FRANK GRACE has left London for New Zealand, to make an examination of the Waihi Grand Junction mine.

H. B. VAILE, of Tunbridge Wells, England, has been visiting the Humboldt-Nevada Mines, Ltd., properties, at Chafey, Nevada.

G. M. ROBERTS of the Associated and the Associated Northern Blocks, Kalgoorlie, Western Australia, has gone to London.

FERGUS ALLEN, manager for the Mexico Mines of El Oro, Ltd., who has been in the hospital at Mexico City, is convalescent.

CHAS. G. YALE, E. W. PARKER, and M. R. CAMPBELL, of the U. S. Geological Survey, left for the East by way of Seattle this week.

E. G. WOODWARD, who has had extended experience in Africa, is consulting engineer to the Ozark Diamond Mines, in Arkansas.

THOS. NUTTAL MILLER, now of the Bullychoop Gold M. Co., will take charge, July 1, of the Texas Jack mine, in Trinity county, California.

MALCOLM MACLAREN is making an examination of mines at Kalgoorlie, Western Australia, and expects to be absent from London six months.

LOUIS A. WRIGHT has been appointed consulting engineer in the Southwest and Mexico for the General Development Co. and to the Miami Copper company.

JAMES S. DOUGLAS, manager for the Phelps Dodge interest in Sonora, Mexico, has resigned and will spend a year visiting the principal copper mines of the world. He is succeeded by J. S. Williams, Jr.

Obituary.

FRANK A. LEE, a mining engineer who was appointed superintendent of the Florence Goldfield Co.'s Goldfield a few days ago, fell down a shaft on June 1 and was instantly killed. He leaves a widow.

General Mining News.

ALASKA.

KETCHIKAN DISTRICT.

The Victor Copper Mining Co. has a group of 18 patented claims on Gravina island, on which there are several parallel veins of copper-iron ore, some of which are contacts between blue limestone and greenstone. The ore is chalcopyrite in a quartz gangue. Much of it is high-grade, and an estimate of the general average places it at 8% copper. To open and develop the property a 6 by 8-ft. cross-cut is being driven, which will intersect the principal contact 2100 ft. below the surface. It starts 40 ft. above tide-water and the work has progressed 550 ft., in the course of which three minor veins have been cut; but to intersect the main orebody the cross-cut must be driven 900 ft. farther. The work is in charge of Patrick Heaney, who states that a steam boiler and a 5-drill air-compressor of the Rand make have been purchased and that this equipment will be installed and in operation by August 1. The work on the cross-cut will then continue till it is in 2000 ft. The Victor company is a close corporation made up of Kansas City and Butte men. The ore carries a small amount of gold.

ARIZONA.

COCHISE COUNTY.

The Princeton Mining Co., whose property is situated in Ramsey canyon, in the Huachuclas, has resumed operations. Frank Littlejohn is superintendent.—Development work on a number of prospects around Benson is exposing ore near the surface. This is carbonate, malachite, red oxide of copper, and some gold. North of Benson some free-milling quartz has been found.—A body of lead carbonate ore was encountered by a cross-cut on the Comanche Chief claim at Duncan. John A. Duncan is the owner of the claim.—A lease and bond has been secured on the Railroad Exchange claim by John Cross and John Buford. The ore is lead-silver and will be shipped to the El Paso smelter.

GILA COUNTY.

The structural steel and a large portion of the machinery has been ordered for the plant of the Miami Copper Co. The mill, which is to have a 2000-ton daily capacity, will be started at 1000 tons and gradually worked up to its full output. It will be constructed so a 1000-ton unit can be added at any time the mine output may warrant.

GRAHAM COUNTY.

The Shannon-Arizona railway has awarded the contract for the grading and construction of the new railroad, which will be 10 miles in length connecting the Shannon smelter with the mines at Metcalf. All tunnels, bridges, and grading will be done for a standard-gauge road, though at present the company plans the laying of a narrow gauge track.

YUMA COUNTY.

A contract for the building of a \$1,000,000 smelter with a 300-ton daily capacity at Parker has been let. The construction will be begun as soon as a spur track from the Arizona & California railroad has been completed.

CALIFORNIA.

BUTTE COUNTY.

The injunction against the Indiana Gold Dredging Co. has been removed and the suit between it and the city of Oroville compromised. The dredging company agreed to pay costs of suit and to level the piles of tailing that were held responsible for last winter's floods.

INYO COUNTY.

The Casa Diablo Mining Co. has received a shipment of electrical machinery from the Pittsburg Transformer Co., consisting of three large and three small transformers. The large ones will be placed at the company's hydro-electric plant on upper Owens river and the small one at the mine. The hoist, compressor, and mill are run by electric power.

MONO COUNTY.

The suit which has delayed the work in the Mono oilfields

has been settled and drilling will be resumed. The Great Western Oil Co. has a well down 1600 ft. and will continue sinking. This well passed through three oil-bearing strata.—The Sierra Co. will start work on the shore of Mono lake.—The Mono Standard Co. struck gas at a depth of 300 ft. that stopped work temporarily.

NEVADA COUNTY.

The Fairview mine near Washington continues its phenomenal production. Eight thousand dollars has been taken out of a raise that is being driven to the surface for an air-shaft. Arrangements will be made shortly for the erection of a 20-stamp mill.

PLACER COUNTY.

The shaft at the Orpheum mine is down 100 ft., and it is the intention of the management to sink 60 ft. more to the adit level. C. E. Peach is superintendent.

SAN BERNARDINO COUNTY.

A. L. White and associates of Lima, Ohio, have taken a bond and lease on the Gold Bar and Gold Bronze mines in the Vanderbilt district for \$500,000. The lease runs over a period of two years. The Gold Bronze shaft is 400 ft. and the Gold Bar 500 ft. deep. The ore assays about \$30 per ton and it is estimated that 200,000 tons is blocked out. The properties have been idle for five years, being tied up in an estate. The Gold Bronze 10-stamp mill will be put into shape to handle the ore.—A shoot of ore running several inches wide and assaying from \$100 to \$400 per ton has been uncovered in the east drift of the Amalie. The main vein continues to run about \$40 per ton. The high-grade will be shipped to the Selby smelter and the milling ore stored until a mill is erected.—The Piute Consolidated Mining Co. has placed an order for a 6-stamp mill and is considering the installation of an aerial tramway to connect the mine and plant.

SHASTA COUNTY.

Four steel cars for the Old Diggings railroad and four scale and two steel gondola cars for the Mammoth Mine railway have been ordered by the Mammoth Mining Co. At their smelter two large settlers will be added and a conveyor for handling low-grade matte installed.—The El Dorado mine in the Tower House district has been sold to W. H. Roller.

The railroad from Delta to the Delta mines on Dog creek is expected to have the line in commission within a few weeks.—The Afterthought Co. is again considering the building of a railroad from Ingot to Anderson by way of Bella Vista. The road has been surveyed and partly graded. The Afterthought mine and Ingot smelter will resume as soon as the road is completed.—One furnace is in operation at the Balaklala smelter and one converter stand.—Active work is going on in the Bully Hill and Rising Star mines and two furnaces are in operation. The Mountain Copper Co. is driving a new adit at the Iron Mountain mine to open a large section of territory that has been carefully tested with diamond-drills. About 100 men are employed in the mine. At the Hornet developments are going on with a small force.

SIERRA COUNTY.

L. P. Woodbury, manager of the Red Star and Rainbow mines at Alleghany, has interested Colorado capitalists in that district and has secured funds for the financing of those properties. The drift will be driven ahead on the vein and a cross-cut started toward the Sixteen-to-One and Twenty-One mines.

The Alaska mine at Pike City is to install a new air-compressor.—The mill at the Willoughby mine above Gold valley is being overhauled and will be started soon to crush the ore that was blocked out in the mine last winter.—The Golden Scepter gravel mine is to be started as soon as the snow will permit. M. M. Vineyard will be in charge of the work. The Bellevue mine is taking out some very rich gravel. The company owns a mile and a half of the channel that is still unworked. A portion of this is in Plumas and a portion in Sierra county.

YUBA COUNTY.

The hull of the largest gold dredge constructed was launched on June 5 at Marigold, a new mining town on the Yuba river. The equipment was made at Marysville and will be installed within the next three months. A depth of 80 ft. will be reached and the amount of gravel handled will be 30% greater than that handled by the other dredges in this vicinity. The approximate cost is \$200,000.

The Guggenheims have closed a deal for the purchase of 160 acres of the Henry King ranch near Bangor, situated partly in Yuba and partly in Butte county. They will develop the land for gold and platinum.

COLORADO.

CLEAR CREEK COUNTY.

Some time during the present month the 500-ft. level of the Virginia City shaft workings will be tapped by the Lincoln Mtn. adit. The bore has been driven for 1500 ft., and surveys show that the objective lies less than 30 ft. distant. F. A. Maxwell is manager.—The Burleigh adit compressor plant has been started, and a number of lessees holding privileges on the Phillips vein have brought machine-drills into use. Hancock & Co. will start shipments of lead-zinc ore to the various custom mills of the district during the next two weeks. Stoping is in progress upon a body of ore that is from 18 in. to 3 ft. wide.—The Scotia mill is to be started at an early date by E. F. Byers.—Farragher & Co., leasing below the 240-ft. level of the Astor mine on Democrat Mtn., shipped 15 tons of second-class ore, the return of which was 97 oz. silver per ton.—Oklun Bros., owners of the Scott property on Republican Mtn., have started a shipment of 20 tons of lead ore. Stoping is in progress and a body of ore is exposed that is from 8 to 16 in. wide, for a length of 75 ft.—The Geneva Extension M. M. & T. T. Co., operating the Star group of claims in the Peru district, has resumed work. The Star vein has been intersected by the adit, a streak of lead ore being exposed that is from 8 to 12 in. wide. E. K. Cass is manager.—The buildings at the Alice mine have been completed, and a force of men is employed grading for the construction of a 300-ton milling plant. A. H. Roller is manager.

OURAY COUNTY.

With the melting of the winter's snow many of the mining companies are breaking trails and increasing their working force. At the Camp Bird a new orebody 14 ft. wide has been opened. As this is in ground that has not been prospected the length of the shoot is unknown.—The Revenue mine continues in good ore and maintains a steady output.—From the Sneffels district from 65 to 68 tons of ore are being loaded on the cars each day, and at the mines 1000 tons are ready to be shipped by teams and pack-trains carrying the ore to Ouray.—The Savage Bear Gold & Silver Mining Co. has opened the trail as far as the Grizzly Bear in order to start operations on its 17 claims. This company is a Colorado corporation, with F. J. Hulaniski as its president. The Grizzly Bear mill has been leased by the company and will be used in milling the ore from the vein and the dump.

SUMMIT COUNTY.

The Sullivan ranch at the mouth of Swan river is to be prospected by churn-drills to determine its value as a dredging property.—The Reliance dredge has just installed a new bucket-line at an outlay of about \$15,000.

SAN JUAN COUNTY.

Machinery for a new mill for the North Star mine has been purchased in Denver and it is expected that the stamps will be dropping in the next few months. T. R. Henahan is superintendent. George C. Hill has been appointed manager of the Highland Mary mine.—The Gold King Mining Co. has commenced re-building their terminal and tram which was destroyed a short time ago by fire. A new vein has been cut and the mill will be started as soon as the tram is in working order.

TELLER COUNTY.

The mines of the Granite Gold Mining Co., the Dillon, Monument, and Granite on Battle mountain and the Gold

Coin in the city of Victor, are operated under the leasing system, and at the present time 30 sets of lessees are engaged in the development of the property. The average value of the ore shipped, including the dump ores, is about \$25 per ton. Dividends amounting to \$16,500 were distributed June 5. D. L. McCarthy is superintendent.—On a 30-ton shipment from the Morris Bros. lease in the Morning Star mine the return was \$40 per ton.—The Humphreys-Thompson leasing syndicate has leased the Necessity claim on Battle mountain.—L. A. Van Tilborg and E. J. Williams, operating a lease between the eighth and fifth levels of the Trilby Mines Co.'s main shaft, have commenced hoisting ore from the seventh level. The ore mined from the main Trilby vein is broken from 5 to 8 ft. wide and is a good milling grade.—The Doctor Jack Pot Mining Co. has declared a dividend of $\frac{1}{2}$ c. per share. The Jack Pot shaft has been re-timbered and the ore will be hoisted through it instead of the old leasing company's shaft.—Joe Couse and partners, operating a lease at the ninth level of the main Wild Horse shaft, have opened an ore-shoot southeast of the shaft and are breaking from 12 to 15 tons per day of milling ore that is estimated at \$12 per ton.—Sinking has been resumed at the main shaft of the Requa Savage Gold Mining Co.'s property on Beacon hill, by the Evelyn Leasing Co. The shaft, now 600 ft. deep, is to be sunk to water-level.—The Altman Leasing Co., operating a five-year lease on the holdings of the Free Coinage Gold Mining Co. on Bull hill, started its new hoisting plant. The leasing company is sinking the Pinto shaft from the 550-ft. level. A station will be cut at the 850-ft. point and the first lateral work by the leasing company will be carried on from that point.—Charles Hathaway, operating a sublease on the American Eagle mine, shipped 30 tons of ore for a trial run.—The monthly measurement of the work performed under the Carlton contract at the Roosevelt Deep Drainage Tunnel shows a total distance driven during May of 954 ft. The distance gained at the Portal heading in the last half of the month established a new record for tunnel driving, in that 246 ft. were run in 15 days.—The Roscoe Leasing Co., operating the Victor mine on Bull Cliffs under a sublease from the Western Investment Co. of Victor, billed out between 450 and 500 tons of ore during the past month, of an average value of \$15 per ton.

IDAHO.

BONNER COUNTY.

The St. Lawrence mine on Antelope mountain shipped five cars of ore on which the smelter return was 16 oz. silver and 75% lead. Joseph Reed is manager.

IDAHO COUNTY.

A diamond-drill is to be installed on the Thunder Mountain Gold Co.'s property on Crooked river. A. R. Balcom is in charge of the operations.—The Horse Shoe Bend placers have been purchased by S. A. Wilson and lumber has been ordered to build a flume to bring water for the giants.—Three feet of free-milling gold ore in a 5-ft. vein has been encountered on the Last Chance Mining Co.'s property in the Elk City district.

SHOSHONE COUNTY.

A saw-mill and six-drill compressor has been ordered for the Interstate mine in the Coeur d'Alene district. Oscar Wallace is manager.—The Idaho Copper Mining Co. has installed a steam-driven three-drill compressor and will install another shortly. A 7 by 9 ft. shaft is being sunk to intersect the vein.—Surveyors for the Idaho Northern Railway Co. are running a line up Beaver creek to tap the Sunset district. They are also surveying to get the grade for a line up the Little North Fork, 12 to 15 miles. There are several good copper properties on this stream on which little development work has been done, owing to lack of transportation facilities.—A good shoot of ore was cut on the 1650-ft. level of the Standard mine at Mace.—The Snowstorm mine at Larson is shipping 10,000 and 12,000 tons of ore per month. Shipments have been curtailed for some time on account of the low price of copper.—The adit of the Teddy Mining Co. cut a vein of chalcopyrite ore

when in 350 ft. The adit will be continued to cut a lead-silver vein 300 ft. farther ahead. J. B. Cox is president of the company.—The Government Gulch Mining Co., near Wallace, has awarded a contract to sink the shaft 100 ft., which will give the company a depth of 200 ft. The company has also awarded a contract for 100 ft. of driving. Some good-looking galena ore was found on the 100-ft. level and it is planned to tap this at greater depth.

MICHIGAN.

Mass has reached the new lode in its cross-cut on the thirteenth level, and the showing is said to be satisfactory. Six hundred and fifty tons of ore is ready for a mill test. —Upon the announcement that the Mass Mining Co. had encountered a good copper-bearing lode at a depth of 1700 ft., the mine management of Adventure, which adjoins the Mass property, immediately began investigations on its side of the dividing line, with the result that on the surface it also encountered what appears to be the same lode. Work will commence shortly by the Adventure Co. on two cross-cuts for the purpose of intercepting this lode at depth. Last year the Adventure commenced diamond-drill operations in the hope of finding some new and profitable lodes. In that search the Mass lode was encountered, but the showing made at that time did not seem to warrant further examination. Three other lodes were also brought to light, one at a depth of 1200 ft., the second at 1500 ft., and the third at 2700 ft. These are entirely separate and distinct from the Mass find. The new vertical shaft will be sunk soon to open these orebodies.—The managements of the Winona and King Philip companies have decided to erect a stamp-mill for the joint use of both companies on King Philip territory, midway between the two mines. Excavating on the site selected, preliminary to the laying down of the foundations of the structure, is now in progress. The mill will have two steam-stamps of 750 tons daily capacity each, and is expected to be ready for service by June 1910. Developments in the Winona mine reveal uniformly good copper ground at and below the ninth level, the ground at depth showing a decided improvement over that opened on the levels above. The company has blocked out upward of 1,500,000 tons of ore ready for stoping. The shaft is sinking for the twelfth level.—Detailed engineers' reports from the Cactus show that a sulphide orebody 200 ft. thick has been demonstrated, with copper content, which averages a little better in copper than Miami and considerably better in silver.—The Lake Copper Co. has entered the lode, with high-grade copper ground, in cutting the station at the fourth level, finding it only 25 ft. from the shaft. It has been cut for a distance of about 8 ft. and is up to the average that has been previously demonstrated in the Lake lode. A diamond-drill is rigged up in the south drift at the second level, about 250 ft. from the shaft, at a place where a trap-rock, believed to be the hanging wall, is exposed.

MONTANA.

LEATHHEAD COUNTY.

Placer gravel which runs \$2 per yard has been found on Howard creek, a tributary to Libby creek, 20 miles south of Libby. The Howard Gulch Placer Co. has bought 820 acres of placer ground lying along Howard and Lake creeks and has a force of men at work doing development and getting ready for the season's run.

SILVER BOW COUNTY.

The fire and gas in the Anaconda, Neversweat, and St. Lawrence mines, which had its origin in the St. Lawrence in 1889, seems to be spreading. The Anaconda mine had to be shut down entirely in the early part of this month, and the gas interfered with operations in the two adjoining properties—the Neversweat and the St. Lawrence. For several months miners have been engaged in bulk heading the workings surrounding the fire-zone in the Anaconda mine. The shaft of the Anaconda was abandoned about six months ago, since which time it has been used only as a vent or chimney for the mine, and the mining conducted through the Neversweat shaft.

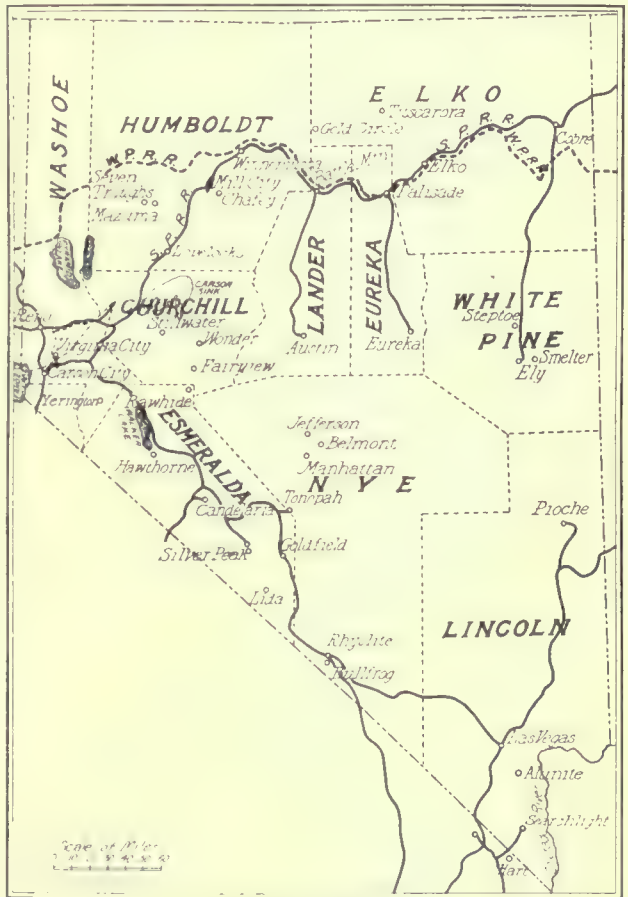

NEVADA.

ELKO COUNTY.

The Oregon Short Line is building from Twin Flats, Idaho, to Cobre, and will furnish transportation for the copper ores of the Contact district. Representatives of both the Guggenheims and the Standard Oil interests have made recent examinations and are both negotiating for a group of over 20 claims. The deepest shaft is on the Brooklyn, where at a depth of 300 ft. an 18-ft. vein has been opened that will average better than 9% copper. The Palo Alto shaft is down 290 feet.

ESMERALDA COUNTY.

Work has been suspended on the Elks Consolidated lease on the Yellow Tiger for a period of 30 days. The shaft is down 707 ft., and it is planned to sink to 1000 or 1200 ft. when operations are resumed. Drifting has been in progress for some time on the 700-ft. level, where a vein 40 ft. wide has been cross-cut, which assays from \$2 to \$5 per ton. Maurice Starne is manager.—Development of the orebody cut by the Victor shaft of the C. O. D. Consolidated, at the 400-ft. level, is now under way. The ore carries a good percentage of copper, but does not assay well in gold as far as developed. The management has determined to sink another 50 ft., as the vein seems to be somewhat broken at

Map of Nevada.

the 400-ft. level.—The Diadem lease on the Great Bend cut a vein of high grade ore. The new shaft of the Nevada Eagles mine has been completed to a depth of 300 ft. The shaft is 8½ by 1½ ft. in the clear, and the machinery will now be moved from the old shaft and sinking of the new will continue to 500 ft.—Shipments from the Marigold lease on the Coalition estate at Rawhide during the last two weeks in May had an aggregate value somewhat in excess of \$12,000. All ores at present being mined are coming from the north and south stopes on the 160-ft. level. At that level a cross-cut is now being run east to reach a vein that outcrops about 200 ft. from the shaft.—An 8-ton consignment of \$150 ore from the Proskey No. 1 lease recently went out to the sampler at Hazen. The shipment was mined from the stopes on the 100 ft. level.—Superintendent Frank McKelvy, of the Victor lease, is pre-

paring for the installation of a 10-stamp mill at a point about 200 ft. west of the shaft.—As the result of the consolidation of the Pittsburg-Nevada and Rialto properties, which has recently been effected, operations have been resumed on the Pittsburg-Nevada. The properties are situated near Knickerbocker mountain, east of Goldfield. A shaft has been sunk to a depth of 264 ft. on the Pittsburg ground, and this will be cleaned out and put in working order.

HUMBOLDT COUNTY.

The Humboldt-Nevada Mining Co., Ltd., of which Edward Stables is manager, is developing a group of 43 claims in the Chafey district. The mine is opened by an adit and shows a vein of gold-silver-lead ore carrying as much as \$72 per ton in gold and \$13 in silver. A shipment of 20 tons to Salt Lake smelters gave a net return of \$47 per ton. English, German, and French capital is interested in the property.

Shipments to the Darby Ore Reduction Co., known as the Harris mill, in the Seven Troughs district, are commencing to come in such quantities as to insure the continuous operation of the mill. The mill has been running one shift ever since it was completed, about a month ago, in order to get it broken in, and the first of the week a second shift was added. E. H. Simonds is temporarily in charge. The mill is now running on Florence ore and will shortly start on 1000 tons from the Fairview. Besides these two there is now in the bins ore from the Hero-Nevada and Prior-Chadbourne lease.—A 280-ft. cross-cut from the 400-ft. level of the Monnette Mining & Milling Co.'s mine has intersected the vein. M. M. Garoutte is manager.

LINCOLN COUNTY.

The shaft at the New York-Searchlight is being sunk at the rate of 5 ft. per day, and the management expects to continue to the 1000-ft. level. A cross-cut is being run from the 200-ft. station.—Fifty-six tons of ore from the Chief of the Hills lease was run through the Cyrus Noble mill. The clean-up resulted in an 8-lb. brick.—The shaft of the Copper Prince mine in El Dorado canyon is down 40 ft. Theo. N. Barnsdale is the owner.

NYE COUNTY.

Thirty miles east of Tonopah a new camp has been established. Salisbury Wash, re-christened Ellendale, is the centre of activity. Some 150 claims have been staked and a town-site located. Ed. Clifford and Joe Nay are the original locators and have a number of claims on the vein, which follows a contact between granite and porphyry. A stringer from ½ to 2 in. wide and 15 ft. long has given samples of almost pure gold, but as yet no development has been done, so the extent of the find is unknown.—The Tonopah Extension Co. started grading for a 30-stamp mill. The mine has been shut down during the construction of the mill.—George L. Bailey, superintendent for the Golden Arrow Mining Co., reports that a strike has been made in the tunnel of the Golden Arrow-Mohawk, about 300 ft. from the portal. The vein is over 6 ft. wide, and is all milling ore, with streaks of high-grade. —The winze from the 200-ft. level of the MacNamara is in good ore. It is in the vein, which is now 6 ft. wide.

WHITE PINE COUNTY.

Both the Nevada Consolidated and Cumberland Ely have decreased their output. A unit has been added to the Steppe smelter and another one will soon be started, as the output of the mines is greater than the smelter capacity. The dredged drill, on the Cumberland Ely, cut a body of good ore of good grade to steam shovel mining. A cross-cut was run on the property of the El Hidden mine, owned by the El Hidden Co. of the Boise-Lansing Co., which will be a good ore vein of the group. This property was at one time a high grade ore, but nothing has been done on it since the copper content was found to be low.

OREGON.

BAKER COUNTY.

The Bate-McKee mine in the Cable Creek district is being reopened by O. W. H. Connor. The 10-stamp mill at the

Humboldt mine in Mormon basin is nearly completed and will start about the middle of this month.—The dredge J. B. Wetherell is building near Gold Center is to commence operations about June 15.—The Kent Ore Reduction Co. has decided to erect a plant in Washington gulch, six miles from Baker City, for treating low-grade ores. The company will also erect a gas plant, using logs and stumps. Henry W. Kent is manager.

DOUGLAS COUNTY.

A carload of oil-drilling machinery has arrived at Oakland, constituting the first lot of drilling apparatus that will soon be at work in this locality, under the direction of the Standard Oil Co., which will sink several wells near Oakland and in the Sutherlin valley. Representatives of the company have been busy the past month in arranging details and getting the leases signed, and now have about 30,000 acres leased for from one to five years. For years this locality has shown prospects of oil, but not until now has it been possible to take up the development of them, owing to the opposition which the representatives have met with in gaining the concessions asked for. The first well will be sunk on the ranch of James Hunt, one mile east of Oakland.

GRANT COUNTY.

George H. Phillips, of Chicago, is operating the Ben Harrison mine, about 15 miles from Granite, on a lease and bond. On the surface the vein has been exposed in a number of open-cuts, and at one point a shaft was sunk 45 ft. on the vein. From this shaft several tons of ore were shipped to the Tacoma smelter, which were settled for on the basis of \$700 per ton.

LAKE COUNTY.

Litigation over the Jumbo Chief claims at Goldberg has been settled out of court and work will be resumed after an idleness of 16 months. A drift has been run 125 ft. on the vein, the assays from which have all been better than \$8.—The adit of the Goldberg Butte Mining Co. cut a vein at a depth of 275 feet.

PHILIPPINE ISLANDS.

The complete equipment for a 20-stamp mill arrived at Manila and was forwarded to the San Mauricion mine at Camarines. This shipment, weighing about 130 tons, was the largest consignment of mining machinery ever brought to the Philippines. It includes a 20-stamp mill, concentrator, an electric-light plant complete, and power machinery. President Heise states that the installation will be complete and the plant in operation by the end of 1909.—The Paracale Gold Dredging Co. reports a saving of 644 oz. and the Benguet Consolidated Mining Co., 235 oz. for the month of March.

UTAH.

BEAVER COUNTY.

The mill at the Cactus mine of the Newhouse company is nearly completed and is expected to start July 1.

JUAB COUNTY.

The Little Silver King mine, recently purchased by A. N. Holdaway, is to be worked through a shaft being sunk on the Tintic Standard property.—The drift on the 500-ft. level of the Iron Blossom mine is in good ore which has given uniform assays of copper, gold, and silver.—Contracts were closed by the Montana Mining Co. of Tintic with the F. C. Richmond Machinery Co. for a complete electrical mining equipment for their property. The machinery includes a 125-hp. compressor, an 8 by 10 hoist, drill, a complete ventilating plant, electric motors, transformers, and all other accessories required.—A five-ton shipment of concentrate and ore was sent to the Tintic smelter by the Lehi-Tintic mine. The ore is high in iron and the smelters pay a premium to obtain this as a flux.

SAN JUAN COUNTY.

Considerable work is being done at the new oilfields 24 miles from Bluff and just across the line from Montezuma county, Colorado. Sixteen wells have been sunk in this

district and all have struck oil. The original well of the region, known as the Ellis and Goodridge, is 266 ft. deep. It is a 'gusher', and produces between 600 and 800 bbl. of oil per day. A new town has sprung up in the field known as Goodridge.

SUMMIT COUNTY.

Work has been started to drain the Wabash mine through the workings of the Ontario. A drift from the No. 2 shaft of the Ontario is now driven 900 ft. toward the Wabash and will be advanced till it taps the Wabash workings. Nicholas Treweek is manager.

WASHINGTON.

FERRY COUNTY.

R. G. Howard, president of the San Poil-Republic Smelting Co., operating in Republic, announced that they have bought land for a smelter-site. The land is below the old flume, and north of the No. 3 tunnel of the New Republic mine and is reached by a spur from the Great Northern railroad. By erecting a smelter at that point it will be possible to better mix the copper and iron ores of that section with the silicious ores of the camp.—The Black-tail mine in the Republic district shipped two cars of ore to the Granby and two to the Tacoma smelter. It is expected to ship two cars per day in July.

CANADA.

ONTARIO.

A contract has been let to sink the Le Roi No. 2 shaft from the 900 to the 1200-ft. level. This will enable the Le Roi No. 2 to tap the Le Roi vein on the 1200-ft. level where it dips from the Black Bear ground into the Annie mineral claim. Below the 1200-ft. level it belongs to the Le Roi No. 2. The estimated cost is \$60 per foot.—Sixty to seventy tons of ore per day are being treated at the McKinley-Darragh mill, producing about three tons of concentrate.—The shaft of the Alexander mine is down 165 ft. and a diamond-drill is being operated from that point. As soon as the drilling is completed the shaft will be sunk to the 300-ft. level and cross-cuts run to the vein from the 200 and 300-ft. levels.—The Cobalt Central is to deepen its shaft 50 or 75 ft.—The diamond-drill at the Beaver mine cut two calcite veins that show a small amount of silver.—Compressed air will be furnished to the mines on August 1 by the Cobalt Hydraulic Power Co. from its Ragged Chutes plant on the Montreal river. To bring the air to Cobalt nine miles of 20-in. pipe will be laid. The loop-line will start from the end of the La Rose bridge and will encircle the town, joining with the main line afterward. In the loop and the various branches around Cobalt the pipe will be 12 in. In addition to the loop there will be branch lines by way of the Colonial and the Nova Scotia. Another line will run to Kerr Lake. A pressure of 110 lb. per square inch will be maintained and the following rates per drill per 10-hr. shift has been fixed for smaller customers: One drill, \$5; two drills, \$4; three drills, \$3.50; four drills, \$3.13; five drills, \$2.80.—In drifting to the west on the 80-ft. level on the No. 5 vein a 4-in. vein of high-grade ore was struck on the King Edward mine on Cross lake.

BRITISH COLUMBIA.

The Nickel Plate mine at Hedley has been bonded by the Daly estate to M. K. Rodgers. The lower levels are now being prospected by diamond drilling.—The Ideka mine on Moresby island, of the Queen Charlotte group, is making arrangements to ship 1000 tons of ore per month to the Tyee Copper Co.'s smelter on Vancouver island. On their April shipment the returns were 7½ copper and \$3.50 gold.

The two recently enlarged furnaces at the Granby smelter have been blown in and the work of enlarging two more of the furnaces is under way. This will increase its gross smelting capacity from 3200 to 4500 tons of ore per day. At present Granby is making copper at the rate of about 22,000,000 lb. per year, at a cost of about 9c. per pound.

YUKON TERRITORY.

The water has been turned on in the Yukon Gold Co.'s

70-mile ditch from Twelve-Mile river. The ditch carries 5000 miner's inches and has taken three years to construct. The Yukon Gold Co. is operating seven dredges with power developed from a portion of the water carried by the ditch.

MANCHURIA.

A company has been formed of merchants of Mukden and Kirin to develop copper deposits in the upper reaches of the Yalu and to build a light railway. Connection with Antung will be made by river steamers.—A report from Dalny is to the effect that Belgian prospectors have found valuable gold deposits near Hailungchen. They will probably be worked by Chinese officials.—The Chinese Eastern railway has placed a small order for Fushun coal with the Manchuria railway and will probably secure its supply entirely from that source if it be found satisfactory.—The Chinese Government has commenced development work on the Kaiping coalfields. The work is under the supervision of German engineers.—The Manchurian Exploration Co., Ltd., was registered in February in London and has for its object the acquiring of grants, concessions, and other privileges in Manchuria, Siberia, and to carry on a general mining and development business.

MEXICO.

CHIHUAHUA.

Several carloads of heavy timbers have been received and active work has commenced on re-timbering the main shaft of La Presna mine in Minas Nuevas. This is the Central shaft belonging to the Hidalgo Mining Co. James I. Long is general manager.—From the 300-ft. level of the main shaft at the Cata-Rica mine a 600-ft. drift is being run on the vein, to connect with another shaft. Both shafts are in ore. This contains considerable zinc, but has been successfully concentrated. W. E. Brock is manager.—The Parral mill, which was recently purchased by the American Zinc Extraction Co., has been thoroughly overhauled and the old machinery replaced by new equipment. Water to be used for the concentrators will be pumped from El Tajo mine, a pipe-line having already been constructed. The Tajo mine, for the treatment of whose ores the mill has been built, has been shut down for the present, on account of no available space in which to store ores, the mine being situated right in the city. About 20,000 tons are waiting treatment on the dumps.—The Palmilla and Anexas mines have been purchased from Don Pedro Alvarado by A. J. McQuatters, president of the Alvarado Consolidated Mining Co. The State Government has granted to Mr. McQuatters and James I. Long a concession to establish a large custom cyanide plant at Parral. The plant will have an initial daily capacity of 250 tons.—The work of connecting the lower workings of the San Cayetano with the upper is progressing as rapidly as safety will permit. The old workings are full of water and making the connection is a dangerous piece of engineering.

COAHUILA.

The negotiations entered into between the International Smelting & Refining Co., and the Cia. Metalurgica de Torreon have been suspended and will not be resumed. The price demanded by the Torreon company was more than sufficient to cover the cost of erecting a new and up-to-date smelter.

JALISCO.

The San Pedro Analco Mining Co. has called an assessment of \$500 per share, payable in monthly installments of \$40 each. The money secured is to be used in completing the company's hydro-electric plant on the Santiago river in the Hostotipaquillo district and in equipping the San Pedro Analco properties with a cyanide plant. Augustin L. Gómez is managing director. The company has worked its ores by the patio process of amalgamation for a number of years.—H. H. Cross and H. W. Young have purchased a 5-stamp mill for the Piginto gold mine in the San Sebastian district. The treatment will be cyanidation, and masonry tanks will be used.

SONORA.

The Porica property owned by Jim Finch and C. A. Overlock, is now under bond to O. L. Neer.

Special Correspondence.

LONDON.

Mining Share Boom. — East Rand Proprietary. — Zinc Corporation Profits. — Hamilton Tube-Mill.

For the first time in years there is a boom in mining shares on the London Stock Exchange, centered chiefly round South African mines. The amount of activity on the Exchange, in the street, and in brokers' offices is reminiscent of the great Kaffir movement of 1895. The present increase in prices differs from most others in that it is founded on solid ground instead of on vague prospects. The settled state of politics and of the labor market, together with the great decreases in costs, have combined to open up vast tracts of gold-bearing country on the Rand, so that the imagination of speculators is readily fired by the golden prospects for the future.

The first of the big amalgamations on the Rand was that of the Farrar group, by means of which the East Rand Proprietary Mines, Ltd., absorbed its subsidiaries, the Angelo, Comet, Cason, Driefontein, and several others not yet producing. The amalgamation was effected on July 1 of last year, and already several events have proved its advantages. For instance, a fire in the Cason shaft hung up the stamps for a fortnight, but by putting extra pressure on the other three mills the total output of all four was kept up. Then again, an accident in the Angelo hoisting plant prevented ore from being raised for a week or ten days, and similar pressure on the other three mills was resorted to. The output has therefore been regular. During the last six months of 1908, the total tonnage treated was 856,320 tons, the extraction 30s. 7d., the costs 16s. 9d., and the profit 13s. 10d. per ton. The ore reserves on December 31 were over six million tons capable of yielding 29s. per ton. The amount of work done is enormous, and large bodies of ore are being developed. Additional plant is being provided in order to bring the total capacity up to 175,000 tons per month. To provide the necessary money, all surplus profits over one million pounds per year will be devoted to this purpose for 18 months. For the purpose of increasing the development, arrangements have been made with the National Bank of South Africa for an advance of £400,000 at 5½%. It is not to be wondered at that after reading news of this sort the London public should take an interest in South African mines.

The report of the Zinc Corporation for the year 1908 contains some details relating to the Elmore vacuum plant which have not hitherto been published. Some mystification has been caused by lumping together in the monthly returns the profits obtained from the concentration process and from the sulphuric-acid plant. The company makes its own sulphuric acid and sells part of it, but as no figures of production are given in the monthly reports, readers could form no idea as to how much of the profit was due to the Elmore plant, and how much to sales of sulphuric acid. By analyzing the figures in the yearly report a fairly good idea can be obtained. During the ten months, March to December, during which the Elmore plant was running, 49,815 tons of concentrate is reported to have realized £2 9s. 4d. per ton, which brings the receipts to £122,877. In the profit and loss account, the total receipts from the sale of concentrate and profit on sulphuric acid are given as £136,398, so presumably the difference, £13,501, represents the profit on sulphuric acid. The total production of sulphuric acid is given as 3129 tons. Probably one-third of this was used in the Elmore plant and two-thirds sold. The great advantage obtained by de-oiling the Elmore concentrate and treating it on Wilfleys so as to dress out some of the lead is also shown in the report. If the concentrate had been sold without further treatment, it would have brought 7s. 6d. per ton. After separating it on Wilfleys, the average price obtained was £2 9s. 4d., an increase which meant an additional revenue of £34,917. The cost of de-oiling and treatment on Wilfleys was £13,575, thus showing a net profit on the re-treatment of £21,342. The company is putting up

a full-size experimental Elmore plant for the purpose of investigating the value of other Broken Hill dumps.

A new form of tube-mill, invented by C. R. Hamilton, is being exhibited in London by Messrs. Attwood & Hopper prior to its despatch to South Africa for trial. The construction is the same as an ordinary tube-mill, but the axis of the cylinder is inclined at an angle of, say, 10 to 20°. It does not revolve round this axis, but round a horizontal axis. The bearings are aligned horizontally as usual, but the trunnions are fixed to the ends of the tube-mill at points between their centre and their circumference. When the mill revolves, the pebbles receive an endward motion as well as a revolving motion, and it is stated that in this way additional efficiency is gained. Results of practical tests will be looked forward to with interest.

WASHINGTON.

Zinc Tariff. — Alaskan Placer Claims and Miners' Liens. — Wages in Mines. — Bureau of Mines Bills.

It is evident that the zinc producers will have to fight to get a duty on their ores. When the zinc schedule was reached in the tariff bill it was put aside for further consideration. The paragraph at present in the bill is that passed by the House, providing a duty of 1c. per lb. on the zinc contents of zinc ore and calamine. This was the condition until Theodore E. Burton, the new Senator from Ohio, introduced an amendment to the tariff bill, placing zinc ore and calamine on the free list. It is expected that the discussion on this schedule will come up within two weeks. Two important bills relating to the mining industry in Alaska have been introduced in the House by James Wickersham, of Fairbanks, Alaska, delegate from that Territory. The first seeks to amend the mining laws so that hereafter no placer-mining claim can be located in Alaska in excess of 20 acres, and provides that no group or association placer mining claim shall be located. If any placer mining claim hereafter located shall be found to contain more than 20 acres, according to the bill, the owner may cast off the excess upon any side or end he chooses. If he fails to do this within a reasonable time, any person may locate the excess upon any side he chooses. The bill provides further that no placer claim shall in the future be located by an attorney or agent for another. Section 3 states that upon compliance with the laws of the United States in all other respects patents for mining claims in Alaska shall be issued whether the boundaries of the claim shall conform to the rectangular system of public land surveys or not, but the description in the patent shall be made to conform to the boundaries of the claim as actually located by the miner. In making the survey the surveyor shall set permanently at every corner of the claim a wooden post not less than 4 in. square and not less than 3 ft. high, each post to be numbered and marked with the name of the claim. The second bill provides for the creation and enforcement of a miners' labor lien in Alaska. Under its provision every miner or laborer whose work directly aids in the production of the mineral shall have a lien upon the dump or mass of mineral-bearing sands, gravels, earth, or rocks, and all gold and gold dust, for the full amount of wages for all the time he was employed. Claims must be filed within 90 days after the work is completed.

The debate in Congress over the tariff bill has brought to the forefront the immensity of the mineral industry in this country. The other day one of the Senators submitted a tabular statement showing the total amount of wages paid by the various industries represented in the different tariff schedules, also the total value of the products as arranged by the schedules. These figures show the wages paid in the mineral industry, including of course the manufacture of the ores into products, as \$863,558,489, out of a total for the entire country of \$2,277,838,543. This is 28% of the total wages paid in the United States.

The United States Supreme Court has just decided that a process can be patented. The decision is expected to put an end to many conflicts. The Expanded Metal Co. had charged Eugene S. Bradford with the infringement of a patent for

the stretching of metal, and the Circuit Court in which the suit was brought granted an injunction prohibiting Bradford from continuing his work. The Circuit Court of Appeals overruled this decision, declaring that patents were not granted on abstract ideas. The Supreme Court overruled the Appellate Court and sustained the Circuit Court. The decision reverses the generally accepted idea of non-patentability of mechanical processes and establishes a rule for this class of patents. The various United States courts have been rendering conflicting opinions.

Still another bill for the creation of a bureau of mines has been introduced in Congress, this time by William F. Englebright, of Nevada City, Cal. The present bill provides for the making of inquiries and technologic investigations on the mining, extracting, and utilizing of the mineral substance of the United States, the treatment of ores, and the methods and conditions under which mines are operated, with a view toward the prevention of mine accidents, of the waste of material, to the betterment of mining conditions, and to the development of the various mining industries; and the investigation of materials of construction, fuels, and other mineral materials belonging to or for the use of the United States Government.

MEXICO.

Protection by Freight Rates.—New Mining Law.—Seguranza Mill.—Cyaniding at Zacatecas.

The new freight rate going into effect June 1 on foreign coal and coke entering Mexico, which amounts to an increase of from 75 cv. to \$1.75 per ton, depending upon the port of entry and the length of haul, has given rise to considerable indignation among the coal producers of Texas, who will be most severely affected. They have had a committee in Mexico City investigating the subject, and as the new rating is applied almost wholly on the merged lines, which are controlled by the Mexican Government, the Texans think they can make it a case of Government discrimination against American products, and it is stated that they will endeavor to have the United States Congress introduce retaliatory clauses in the new tariff bill. The Mexican coal producers claim, however, that it is in no sense a Government discrimination against American coal and coke, as there are no duties against either, and that the new rates simply put the foreign product on the same freight basis as the home product. Whether the Texans will attempt to, or can, prove their case, remains to be seen.

The proposed new mining law which was left over from the last Congress has been discussed and disposed of by the Chamber of Deputies and has now passed on to the Senate. It is understood that endeavor will be made to rush it through so that it may go into effect July 1, 1909. The bill was thoroughly considered and discussed, article by article, in the lower house, and the greatest opposition was manifested against the arbitrary power given the Minister of Fomento (Secretary of the Interior) and his department, from whose decision there was to be no appeal. These articles were so changed that one may have access to the courts of the country when it appears that justice is not being obtained from the Department of Fomento. Thus individual rights are more closely protected.

In the Zacualpám district of the State of Mexico, the Seguranza 100-ton concentrating and cyaniding mill is nearing completion and would be ready to go into commission before the end of June were it not for the electric power-line, a branch of the Sultepec Electric Power Co. line, which will not be completed into Zacualpám before the end of July or the beginning of August. The starting of the Seguranza mill will immediately follow. The \$25 per ton freight haul to the railroad has made this mill necessary, and it has been so constructed that the capacity may be increased by 50 or 100 tons as soon as the amount of custom work demands the increase. At present it is counting principally upon its own ores and those of the Olvidada mine, where a good body of 50-oz. silver ore is being blocked, pending the completion of the Seguranza plant. The old

Concepción is again showing a large, rich body of silver ore, and at the Cuchara a 50-ton concentration mill is being built.

Zacatecas continues to figure on important improvements ahead. The new plant of 100 tons capacity—Chilean mills and cyanide equipment—at the Bote mine, is practically completed, and will at once begin treating the old dumps and mine fillings. Plans are also once more under consideration for treating with cyanide the enormous piles of old tailing on the patios at Guadalupe, below the city of Zacatecas. Examinations are being made of the Austuriana on the old Veta Grande with the view to resuming operations. At Fresnillo, the Fresnillo Mining Co., one of R. S. Towne's many enterprises, which for six years has been lixiviating with hyposulphite of soda some 2000 tons per month the old tailing dump, presumably from the Proano mines, is making alterations in the plant, whereby a much larger tonnage may be handled and cyanide introduced in place of hyposulphite. Other parties have been planning to quarry the Proano mountain at Fresnillo, which it is said will assay about 400 gm. (12 oz.) silver per ton, and cyanide

Zacatecas.

everything as it comes, but there seems to be some hitch in carrying out these plans.

SALT LAKE, UTAH.

Copper Output.—Knight Mines & Smelter.—Jackling in Yerington.—Newhouse Holdings.

Copper producing mines of Utah have again reached the 10,000,000-lb. mark. During May the output of the red metal from the Bingham mines was maintained and the high mark set in April was again reached. Utah Copper has reached its maximum capacity of 5,000,000 lb. from its mill plants at Garfield and Copperton, the former with a capacity of 6000 tons and the latter of 1000 tons of crude ore daily. The Boston Consolidated again produced something over 1,500,000 lb., and other mines the usual tonnage. The Boston Consolidated will increase its production as soon as the last two sections of the mill at Garfield are commissioned. Railroad facilities for transportation are satisfactory, and improvements in the 'ore-line' and additional equipment in engines and cars give assurance that there will be no further delays.

Jesse Knight has just issued a statement of the conditions at the Tintic smelting plant at Silver City. He says the company is operating four lead-furnaces, having a capacity of 225 tons each, and one copper-furnace of similar capacity. Until recently there has been a heavy expense in making alterations and additions to the smelter. Now it is making some profit. Within a few months, says Mr. Knight, the company will show a good profit on the original investment of about \$1,000,000. Regarding the deal for the Tintic smelting plant, the Colorado, and the Iron Blossom mines, it is learned that the United States Smelting Co. and the International have each submitted bids. The American Smelting & Refining Co. has agreed to have a bid ready within a couple of weeks. The United States bid will not be considered, as it is too low. The Cole-Ryan bid is more satisfactory, and unless the American bid is higher it seems probable that the International will be the owner of the mines and smelting plant within 30 days. Good progress is

being made in the construction of the International smelting plant. Excavation for the foundation has been completed, and E. P. Mathewson, general manager, says that they will be prepared to receive both lead and copper ores by the first of the year. The advent of the International will give Utah operators four smelting plants, and will make this the largest smelting centre in the world.

Overtures have been made to D. C. Jackling to become interested in the copper mines in Yerington. The Blue Stone property, owned by J. R. De Lamar, and the Mason Valley, have been mentioned, but Mr. Jackling says that he has no time at present to consider these propositions. At one time he held a large block of Mason Valley, but disposed of his interests in this company several months ago, and re-invested his money in the Ray Consolidated, of which he is general manager. He is devoting his personal attention to directing the affairs of the Ray and Utah Copper companies, and while he will take some part in the re-organization of the Santa Rita Mining Co., to be known as the Chino Copper Co., he will not assume the personal management.

Samuel Newhouse is devoting most of his time to the direction of his personal holdings in Utah real estate. The Boston Consolidated's and Newhouse Mines & Smelters Co.'s operations are directed by executive committees chosen from among the directorate. The Newhouse holdings in each of the companies are not so large as formerly, though he claims that his confidence in the outcome of these mines is as strong as it has ever been.

KALGOORLIE, WESTERN AUSTRALIA.

Sons of Gwalia.—Ivanhoe. — March Output. — Australian Institute.

A few good developments have relieved a dull month. The Sons of Gwalia announced the cutting of the Sons of Gwalia South shoot in the west cross-cut, at level 14, the lode being 41 ft. wide and worth \$12 per ton. This is a really fine development, and the Sons of Gwalia is our most important outside mine, as the Bellevue, Cosmopolitan, Great Fingall, and others which were noted producers, are only working on a small scale. The Sons of Gwalia ore is a schist cut by quartz. It is worked by means of a large incline shaft. Self-dumping skips tip the ore into jaw-crushers of the Blake type, the broken ore dropping into a small storage hopper, from which it is taken to the mill-bins by belt conveyor. Fifty stamps of 1100-lb. weight each crush the ore through a 20-mesh screen, and the coarse gold is caught on amalgamated copper plates. The pulp passes over 10 Wilfley tables, and is then elevated by a large tailing-wheel to the classifiers. The coarse sand from the first classifier runs to three 5-ft. grinding pans, passes over two Wilfley tables, and is again elevated by wheel. The pulp from the second classifiers then flows into eight steel collecting vats by means of the usual distributors. The sand is given a preliminary wash and is then dropped into a second set of vats for further treatment by cyanide, after which it is discharged. The slime overflow from classifiers and collecting vats is run into V-shaped settlers, and agitated, being finally treated in a Cassel plant of the usual design. The concentrate from the Wilfleys is dried somewhat, passed through an Edwards roaster, ground in a 5-ft. pan with KCN and Hg, run into small agitators, treated with KCN, and finally filter-pressed. The monthly output amounts to 13,389 tons yielding \$100,000, of which \$31,000 is profit.

At the 1970 ft. level in the Ivanhoe the cross cut has gone through the east lode, it being 33 ft. wide and worth about \$7 per ton. A fault has affected the orebody at this point, as in the upper levels; but driving usually reveals good ore beyond. The ore reserves are now published as 934,089 tons, averaging \$11.75 per ton. The No. 3 lode in the Golden Horseshoe was cut at the 2000-ft. level, the width being 7 ft. and value \$15 per ton. The reserves amount to 1,065,409 tons worth \$12 per ton. Driving north from Hamilton shaft in the Great Boulder, at 1500 ft., the Ivanhoe east lode has a value of \$14 over 41 ft. width. The ore reserves in the Great Boulder total 711,126 tons worth \$10 per ton. The

new vertical hoist, head-gear, breaker station, and conveying system are in full working order. The Lake View Consols reserves are stated to be 174,189 tons at \$6.60 per ton; the Associated, 483,517 tons worth \$10 per ton. The Associated has now got its large surface condenser at work, also a new Bellis-Morcan generating set for power and lighting. Five A. Z. agitators now deal with all the mill pulp. The Kalgurli company is now sinking below 1600 ft. Fair results are being met with below 2000 ft. in the Great Boulder main reef. The North Kalgurli is erecting another 10 stamps, making 20 in all. This property is worked mainly by tributors, but it has been lately re-sampled with a view to the company working it. The Lancefield, some 200 miles north of this centre, is at work again. It appears that graphite is the great trouble in treatment up there, and not so much the arsenic, of which he heard so much. The March gold output from the State was valued at \$2,700,000, and for the year to date \$8,000,000. The returns from the principal producers in March are as follows:

Name.	Tonnage.	Value.	Profit.	Dividend.
Associated	11,718	\$115,000	\$35,000
Associated Northern Blk. 3,750		33,000	14,000
Golden Horseshoe	25,103	255,000	100,000
Golden Link	4,066	33,000	*1,500
Golden Ridge	2,280	28,000	14,000	\$31 000
Gt. Boulder Proprietary..	16,259	247,000	130,000	325,000
Gt. Boulder Perseverance.	18,725	140,000	31,000
Great Fingall	14,268	70,000	400
Hainault	5,010	30,000	2,500
Ivanhoe	19,307	215,000	105,000
Kalgurli	10,900	142,000	80,000
Kalgurli South	9,039	61,000	13,000
Lake View Consols.....	7,367	60,000	14,000
Oroya-Brownhill	11,580	100,000	37,000
Oroya-Black Range	4,718	59,000	22,000
Sons of Gwalia	13,389	100,000	31,000	60,000
Sons of Gwalia South....	2,050	26,000	7,500

*Loss.

At the end of April, the Australasian Institute of Mining Engineers met here. It is about eight years since they met here last, and that meeting was characterized by some lively discussions on treatment, as the present processes were not perfected at that time.

TORONTO, CANADA.

Cobalt.—Elk Lake.—Gowganda.—Alberta Petroleum.

An important strike was made at the Beaver mine, in Cobalt, May 14. A vein 10 in. wide, assaying some 4000 oz. silver per ton, was discovered in an adit 50 ft. east of the main shaft at the 200-ft. level. The significance of this find lies in the circumstance that extensive development on the upper levels led to no discoveries of value, leading to the conclusion that deep mining is necessary to realize the possibilities of the camp. The strike had an immediate effect on the stock-market, the shares which had been selling for about 18c. suddenly doubling in price. Good ore is being taken out, and the Beaver will shortly figure in the shipping list. A massive nugget has been found a short distance below the surface on the Cobalt Gem property, in which Philadelphia capitalists are largely interested. It weighs approximately a ton, being 5 ft. 6 in. long, 2 ft. 5 in. wide, and 16 in. thick, and is 75% silver. It will be sent on to Philadelphia. Systematic surface prospecting on the location has been begun. The La Rose is extending its workings by cross-cutting under the track of the Temiskaming & North Ontario railway to reach its holdings on the town side of the railway hitherto undeveloped. The ground will be worked from the first level of the La Rose. The new vein of the Lawson property, now owned by this company, has been stripped for 28 ft. and yields high-grade ore, carrying much native silver. A strike has been made on the Paymaster 120 ft. from the shaft at the 100-ft. level, where a small stringer has developed into a 2½-in. vein of solid cobalt carrying silver. At the Otisse-Currie in the Montreal River district, another shaft is being sunk. At a depth of

6 ft. the vein shows about 7 in. wide and carries cobalt, galena, and silver. The main shaft is down 71 ft., the vein maintaining its quality.

Elk lake is now accessible, navigation having opened. The first boat from Latchford arrived on May 19. Since then regular trips are being made twice a day. In Smythe township several promising properties have been opened up in the diabase belt. Among the best is the Watts. A stringer, after being followed down 23 ft., has widened to a vein of 3 to 4 in. with high silver content. The Langham and the Gavin Hamilton in James township, both equipped with compressor plants, promise to become shippers shortly.

Gowganda is still cut off from the outside world, and most of the mines are out of communication with the town, so that authentic news is difficult to obtain. From all accounts little actual mining has so far been done. A quantity of ore has been sacked at the Boyd-Gordon, and ore is also being taken out at the Bartlett, Reeve-Dobie, Silvers Limited, and some others. But it is likely that it will be necessary to store the output until the winter roads are available for transportation, making perhaps a few sample shipments of high-grade ore by freight canoes or wagons at enormously high rates. A large influx of prospectors and mining men is anticipated as soon as the region becomes more accessible. The almost prohibitive price of lumber is felt as a serious drawback to the camp. Owing to the high price of labor and excessive stumpage dues charged by the Government, rough lumber costs \$70 per thousand feet, and dressed lumber from \$80 to \$90 per thousand, so that tents and log-houses take the place of frame buildings.

Eugene Coste, of this city, has for some time been making an inspection of the petroleum and natural gas field at Bassano, Alberta, 83 miles east of Calgary, for the Canadian Pacific railway, and has reported that in all probability natural gas exists there in large quantities. His opinion is that a series of gas pockets follow the same strata as those from which the supply of Medicine Hat is drawn. The company has accordingly commenced boring operations in the hope of securing gas in sufficient quantity to supply Calgary. D. D. Cairns, of the Canadian Geological Survey, and party has left to investigate the copper, silver, and gold deposits of the Watson and Wheaton districts, Yukon Territory.

BRITISH COLUMBIA.

Dominion Copper.—Granby.—Geological Survey.—Nugget.—Consolidated.—Mining Institute Meeting.—Le Roi.—Production for 1908.

At the sale of the property of the Dominion Copper Co. only \$150,000 was bid for the several mines, smelter at Boundary Falls, and most of the supplies, while but \$5000 was bid for the supplies designated as lot B. The only bidder was M. Weinman, representing the re-organization committee of the bondholders. The sale was postponed until June 3, when it is expected there will be other bidders. The sum of \$155,000 will not go far toward reimbursing the bondholders their \$800,000, and other creditors the further sum of nearly \$100,000. Ore shipments from the Granby Consolidated mines showed a small increase during the week ending May 28, and this will very likely continue during the ensuing week, as two more of the enlarged furnaces have been blown in, and the work of enlarging No. 5 and 6 has been started. It was expected that this work would have been completed in July, but the smelter has been kept so busy that it will be some time in October before the eight furnaces have been altered. The new furnaces are giving good results, and what was partly an experiment has proved a big success. The Granby Co. put in an 8 by 12-ft. triple pump last week, placing it on the 400-ft. level, from which point it will be used to pump water to a tank 500 ft. up the hill. The Geological Survey of Canada expects to do more work this year in British Columbia than ever before. Extensive mapping will be done in the Tulameen district. O. E. LeRoy and assistants have just completed detailed work in Phoenix and have left to take up work in the Slocan. Mr. LeRoy is also working on a geological map of Sheep Creek district. A survey of the West

Fork of Kettle river will be started this summer. Texada island, Vancouver island, the Skeena River section near Hazelton, southwestern Yukon, and the Fort George region, as well as the coal areas near Telkwa, will all receive attention this summer, parties having already departed for the various districts named. The identity of the capitalists for whom M. K. Rodgers has bonded the famous Nickel Plate mines at Hedley has not as yet been revealed. The property has been thoroughly sampled. Two years ago the Nickel Plate concentrate had to be hauled 50 miles to the railway; in a short time this product can be loaded on the cars at the mill door and shipped over the Vancouver, Victoria & Eastern Railway (Great Northern).

A new small vein was cut in the tunnel now being driven on the Nugget, near Nelson, last week. The strike occurred about 70 ft. from the portal of the adit. The Nugget mill is turning out a gold brick every two weeks valued at from \$4000 to \$5000. Last week the Consolidated company acquired the Alice mine at Creston, 60 miles west of its St. Eugene property, at Moyie. The Alice is a silver-lead mine of promise. There is a 60-ton concentrator on the ground. The Consolidated Mining & Smelting Co. of Canada; Granby Con. Mining, Smelting & Power Co.; British Columbia Copper Co.; Le Roi No. 2, Ltd., and Le Roi mining companies, all recognize that the life of a mine is short. The first three of these concerns are investing in mines and have up-to-date smelting, converting, and refining plants in operation, while the other two are emulating their example as far as their means will allow. A meeting of the Canadian Mining Institute was held at Coleman, Alberta, on May 26, at which the usual routine business was carried through and papers read on rescue apparatus for coal mines, progressive mining, and other subjects. The silver-lead mines of the Nelson district have just received from G. O. Buchanan, Kaslo, checks from the Dominion Government for the bounty on the lead content of their ores to March 31. The McGillivray Coal & Coke Co., Coleman, Alberta, has decided to build 10,000 ft. of electric road from its mine on McGillivray creek to the Canadian Pacific railway main line. A steam-power plant will also be put in shortly. Byron E. Sharpe, Spokane, Wash., is secretary.

The Le Roi No. 2, Ltd., has planned to expend about \$18,000 in deepening the Josie shaft from the 900 to the 1200-ft. level. One of the rich Le Roi lodes extends into the Annie claim of the Le Roi No. 2 at about this depth, and as the ground has been partly proved with diamond-drills, it is expected good results will be obtained from this work. Another copper furnace has been blown in at the Trail smelter of the Consolidated company. This is one of the largest copper furnaces in Canada, and is the fourth put in operation at Trail. Mechanical feed is being installed at the big lead furnace at Trail. It is said by the management that this lead furnace smelts more ore daily than any other lead stack on the continent. It has made as high as 98 tons of lead bullion in 24 hours. As we pointed out at the end of 1908, there was a small increase in the metallic production of this district, while the coal-mining industry just about held its own. A preliminary report on the mineral production of Canada in 1908 shows that there was an increase of about half a million dollars. The output was valued at something over \$87,000,000, as against a figure under that amount for 1907. But for the slump in metals the value of the output would have been \$8,000,000 more than it was. Silver showed an increase of over 72% (the lead bounty may account for part of this); gold and copper also showed increases. Iron, lead, and nickel showed a slight decrease. It has been nine years since gold showed an increase. The Yukon output increased as well as that of British Columbia, most of the precious metal in the latter case being mined by the Rossland-Trail Creek mines. The placer gold output was 44% of the total, quartz mining being credited with 56%. The copper output was 64,361,636 lb., an increase of 14% over 1907. The British Columbia increase was over 7,000,000 lb., of which a large part was mined in the Boundary district. All of the \$1,920,487 lead output was mined in British Columbia. The coal production in British Columbia was \$7,280,000, against \$7,390,306 in 1907, being 2,329,600 tons and 2,364,898 tons, respectively.

GOLDFIELD, NEVADA.**Florence Goldfield Dividend.—Consolidated Shipments.—Combination Fraction Development.—Grand Jury Indictments.**

Announcement is made that the Florence Goldfield Co. will pay a dividend on June 15 amounting to 10c. per share, a total distribution of \$105,000. This will be the fifth dividend of the company, the former payments, made last year, being entirely from money received as royalties from lessees. The work of enlarging the Florence mill is now going forward rapidly. Grading is in progress at the south side of the plant, where the walls of the structure are to be moved a distance of 40 ft. to accommodate the additional machinery, which will consist of a tube-mill, plates, and several Card concentrating tables. In addition to this new equipment the company has secured a high-power pump for the main shaft and an air-compressor for the cyanide department. The grade of ore being treated is maintained at about \$25 per ton, the product being taken from the company workings above the 350-ft. level and from lease dumps. The raise to connect with the main shaft from the 500-ft. level of the Engineers' workings has still nearly 100 ft. to go to complete the connection.

The Consolidated company is shipping bullion at the rate of one bar daily, the output for 36 days past being valued at \$597,350. For the month of May the bullion shipments were \$511,050. From 12,305 tons of ore mined during May the estimated gross extraction was \$767,000, the total cost of production \$145,000, and the net profit to the company \$622,000. Shipments of high-grade ore from the Hampton stope have been less than formerly, and every effort is being made to treat as much of the product as possible while keeping the mill heads at the desired figure of \$35 per ton. The ore shipped has averaged \$800 per ton, though some has exceeded that value. No high-grade ore has been hoisted during the past week, and that which is broken in further opening the Hampton stope is stored in the workings. An increased production is being made from the Mohawk mine, while 150 tons daily are being taken from the new stopes of the 260-ft. south drift on the Red Top and Lucky Boy. Both mills of the company are treating nearly their full capacity of ore daily, and the new mill has at times exceeded its rating of 600 tons daily.

A regular production of 85 tons per diem is maintained by the Combination Fraction mine, the product coming chiefly from stopes above the 450 and 200-ft. levels, while at several points between good orebodies are being developed. The long cross-cut at the 600-ft. level is being driven toward the Hampton stope vein of the Combination. The Little Florence lease on the southern portion of the Fraction has been declared forfeited, and the parent company has taken possession of the workings. The leasing company has been unable to perform the work required by the terms of the lease, and since the first of the year has been operating with funds subscribed by the directors. The Daisy mine is making a profit from the output of 10 tons of ore daily, and is developing on an extensive scale at four levels, employing over 50 miners. At the 500-ft. level the main lead has been cut, and a drift is being driven toward the ore-shoot from which production is being made at the upper levels.

The Esmeralda county grand jury on June 4 returned indictments against the officials of the Pittsburg Silver Peak and the Florence Goldfield M. Co., the former at Blair and the latter at Goldfield, on the charge of conspiracy in attempting to defraud the State of Nevada of its bullion tax. The officers of the Pittsburg Silver Peak are William Flynn, president; George T. Oliver, vice-president; T. J. Crump, secretary and treasurer; John S. Weller, general counsel, all of Pittsburg, Pa.; Edmund Juessen, consulting engineer, and George O. Bradley, manager, Blair, Nev. The directors are Ralph E. Flynn and J. G. Splane, both of Pittsburg, Pa.; Charles Y. Fuller and M. A. Carton, of Utica, N. Y.; Frank Knox, Salt Lake; and J. H. Brown, Wilmington, Del. George T. Oliver is the newly elected Senator from Pennsylvania. He has denied any personal knowledge of the facts, and states that he had only incidentally learned that there was some matter of taxation in dispute between the company

and the State, and he was personally satisfied that no illegal acts had been committed as charged. The company's annual statement to the stockholders shows a large profit from last year's operations, while its statement to the bullion tax collector shows no net profits. Charges against the profits of \$4 per ton for milling are made, whereas the books of the company show the cost of milling to be only \$1.10 per ton, it is claimed. It is stated by the district attorney's office that the directors and officers of the company were cognizant of the false charge against the profits, and sanctioned it, and therefore are guilty of conspiracy. A report made to the stockholders on February 17 shows a net earning for the preceding fiscal year of \$348,482.

The officers of the Florence Goldfield Mining Co. are: Thomas Lockhart, president; A. D. Parker, vice-president and treasurer; A. M. Lockhart, wife of the president, secretary; and E. B. Parker, wife of the vice-president, and E. S. Vandyck, directors. Mr. Parker is vice-president and general manager of the Colorado Southern at Denver, and Lockhart is one of the best known mining men in the State. The Florence is a highly profitable mine, the output from its mill being \$55,000 per month. It is stated that the Florence has charged against its profits losses made by unproductive leases operated by others on the Florence ground, while the company collected royalties in large amounts from the productive leases, but did not include the amounts in their bullion tax returns.

BUTTE, MONTANA.**Colorado. — Low Rates on Silver Ores. — Raven Re-organization. — Great Falls Smelter. — Tredinnick Process.**

The Davis-Daly company has started sinking in the Colorado shaft. The shaft is now down 1480 ft., and it is the intention of the management to continue the sinking as rapidly as possible until 2000 ft. is reached. This will take about six months, and by that time it is expected that the available ore supply will be such as to justify the re-opening of the big concentrator at Basin, formerly operated by Heinze.

The low freight tariff on silver ores which the Chicago, Milwaukee & Puget Sound railroad has agreed to put into effect from Fergus county to Anaconda, with a lower treatment rate granted by the Washoe smelter, will enable \$12 ore to be handled at a profit. The re-organization of the Raven Mining company is now taking place. There are at present 630,000 shares of stock outstanding. Stockholders will be asked to subscribe, share for share, to stock in a new company, which is to have an authorized capital of 1,250,000 shares, par value \$1 each, by the payment of 25c. per share, payable in installments of 15 and 10c. The officers of the Butte & Ely Copper Mining Co. have ordered resumption of work on their properties at Ely, Nevada. Development was suspended two years ago. Ore had then been found in three shafts. It is now proposed to test other holdings by churn-drilling. That the Boston & Montana smelter at Great Falls is to be enlarged and improved has been stated by C. W. Goodale, the superintendent, following a visit to the plant by Benjamin B. Thayer and John Gillie.

Adolph Wetzstein, of Butte, and Stephen Tredinnick, formerly of Butte but now of Omaha, have invented and patented a process for desilverizing lead bullion, which is now being installed in the Omaha plant of the A. S. & R. Co. Argentiferous lead ores are usually low in silver, and the cost of refining by the ordinary processes is stationary. By the Tredinnick process the cost is on a graded scale proportional to the amount of silver carried. Missouri lead containing only half an ounce of silver per ton may be desilverized at a cost of only 15c. per ton, according to L. S. Austin. Thus the cost of concentrating and desilverizing the several grades of lead bullion would vary from 15 to 64c. per ton. To this must be added the cost of treating the drosses, the first melting, and final molding of the market lead, which will run about 25c. per ton. An improvement on the process is now being made which will permit two or more crystallizations on the same charge and kettle. The extra crystallizations will eliminate the bismuth, or render it below the limit.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Mining claims in any number may be located by a single individual, or by any association of persons. The only limitation is the greed of the locator.

Bismuth extraction from ores by a hot alkaline solution was patented by Stanley C. C. Currie, May 16, 1904, U. S. patent No. 881,101. We do not know whether the process has been applied industrially or not.

Location notices should be complete enough in description to clearly define the ground claimed, so that it might thereby be identified by others. The notice posted on the ground, and the one recorded with the county or district recorder should be exactly alike.

Ore 'frozen' to the wall in a granite country, in itself has no significance. The meagre data submitted allows no important deductions to be made, but the circumstances suggest the possibility that the so-called orebody is in effect a highly acid (silicious) pegmatite dike, or it may be a vein resulting from segregation of silica.

Kaolin, washed and ready for market, is worth from \$8 to \$9 per ton in New York. A royalty of 50c. per ton gross on the mineral in North Carolina would be excellent compensation. The costs of mining, preparation, and shipment will leave only a reasonable profit for the operator after paying such a royalty, even when the kaolin is of high grade.

Custom waives close adherence to the letter of the law in the matter of including among the 'locators' of a mining claim those not actually on the ground. Nevertheless the law concedes possessory title to discoverers, and in consideration of such discovery. In strict construction of the law those who did not share in the discovery could not make good their claims to an interest in a partnership location.

Estimation of lime by the sugar method consists in determining the hydrate or available $\text{CaO} \cdot \text{H}_2\text{O}$, taking advantage of the solubility of that substance in a solution of sugar. The carbonate is insoluble in sugar. The lime is agitated with sugar-solution, and filtered, after which the lime is estimated by the ordinary alkalimetric method. Forty parts of sugar in 100 parts of water will hold in solution $11\frac{1}{2}$ parts of CaO .

Criadero is the name given to a mineral deposit in Spanish. It means literally the place where a thing is created. The character of the deposit is stated by modification of this word, as 'criadero en veta', a vein deposit; 'criadero detrítico', an alluvial or placer deposit; 'criadero en filón', a vein of considerable longitudinal extent; 'criadero bolsado', an irregular mass; 'criadero en manto', a bedded deposit; and 'criadero en riñones', lenticular (kidney-shaped) orebodies.

Mercuric chloride (corrosive sublimate) reacts promptly with copper, forming copper chloride, and depositing mercury, which amalgamates with the

copper. This is a good method for re-amalgamating bare spots on plates in gold mills. The surface treated must be well washed first with a solution of lye, and that in turn thoroughly washed out; after which silver amalgam may be rubbed in. A surface so prepared should start catching gold as readily as on old, 'well soaked', electroplated copper plate.

Gold, even when coarse, is reduced to a fine state, exceedingly favorable for cyanidation, by tube-mill grinding. Although modern practice inclines to cyanidation, it must be borne in mind that in some gold ores cyanicides are present which cause a consumption of cyanide which often becomes economically prohibitory. Amalgamation is often effected more readily after tube-milling than after simple stamp-milling of the ore. In cases where cyanide consumption is excessive it would be well to test the possible extraction by plate amalgamation after tube-mill grinding.

Partnership claims are generally located jointly, that is, the discoverers all sign their names to the location notice. This should, however, be done only when they actually are joint discoverers; otherwise the actual discoverers should make the location, and then include other partners by an assignment of their due interest. In mining parlance, one partner will 'locate in' the others, merely to avoid the routine of making the assignment, and the cost and inconvenience of having it acknowledged before a notary. Such an assignment also must be recorded, adding more rigmarole and cost.

Abandonment of a group of claims has no influence on present rights under re-location, if there be no adverse claimants. The question propounded reduces to that of validity of assessment work done on one claim only, to cover the entire group. If the development is manifestly for the benefit of the entire group, the work so concentrated at one point will apply; for example, if the group covers a vein which extends continuously through the several claims, a shaft on one might benefit all, on the assumption that levels would be driven at different depths, developing the vein in its total extent.

The Hoepfner zinc process adopted by Brunner, Mond & Co. consists in roasting the ore and leaching the metal out as a sulphite with SO_2 solution. This is oxidized by aeration, and the zinc sulphate converted into chloride by salt (NaCl). The electrolyte is a solution of zinc and other chlorides; the cells are divided into anode and cathode compartments by diaphragms. The cathodes are rotating discs of zinc, only partly immersed in the electrolyte; the anodes are carbon or lead. Mond substituted revolving rolls for the discs. The zinc sulphate solution may be chloridized by mixing with the waste calcium chloride, liquors from the ammonia-soda process. Calcium carbonate ('pearl-hardening') in a form desired by paper makers is thrown down as a by-product, and chlorine gas is liberated at the anodes, available for making bleaching powder. The zinc obtained by this process is particularly pure, and is valuable for making brass for cartridge cases.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Designing Mine Equipment.

The Editor:

Sir—Under the above heading, in your issue of May 8, is an article from P. Schreiber, of the Arthur Koppel Co. Mr. Schreiber's main point is, that manufacturers of mining equipment should do the designing and make alterations to suit various conditions. I agree with him perfectly upon this point; furthermore, it has become a thing of the past for the chief engineer of a mine to undertake the design of something that is standard among manufacturers. I wish to discuss the question of designing in a little broader sense than Mr. Schreiber has done, that is, how to get the best equipment for the least money.

In the building of a surface plant, a mill, a smelter, or whatever the conditions require, there are two kinds of equipment. One is the standard article, made by the manufacturer, the other is the special thing that connects the various standard machines. For example, an engine is standard, a blower is standard, but the air-pipe that connects them, is special. It is the business of a chief engineer who represents his company economically to know a good article of manufacture when he sees it, to know how to arrange it for the work it has to do, and above all to know how to design in detail anything that is special. If the special design pertains to a machine itself, the manufacturer certainly should be consulted. The chief engineer who knows it all has probably only been out of school a short time. As he grows older he will know less, and will be paid more for what he does know. Again, this special thing which is designed by the chief engineer, is made up of a number of standards. The pipes have standard flanges and valves. The steel plates and angles used are standard, in so far as stock sizes and quantities are concerned. The advantage in having the chief engineer at the plant design in detail, is the saving in time and the competition in prices. An entire equipment can be installed and in operation in the time consumed by the various manufacturers in finding out what is wanted. The chief engineer shows his wisdom in allowing manufacturers to make changes and suggestions that will cheapen the cost but not alter the value.

How can the chief engineer reduce the first cost? Suppose the mine is at a considerable distance from the manufacturers. The mining company wishes to get competitive prices. Are each of the manufacturers to send a representative to the mine, find out what is wanted, and then submit prices? Are the manufacturers going to do this consulting work for nothing? Most makers of mining equipment maintain a designing department. It is next to impossible to do business any other way. These designers have their troubles, the chief one being the impossibility of getting engineering information from the field.

It is not a designer's business to create information; it is his business to create the proper equipment after he knows the conditions in the field. Here is where the chief engineer is a saving to the mining company. He can express in engineering language exactly what is wanted. He can give all the outline dimensions that the shop designer needs to complete a proposal. The manufacturer quotes the lowest price from the start, because he knows exactly what is wanted. The mining company can install a variety of machines, selecting what is considered best for the purpose; the chief engineer's business being to see that all special connections are provided for. Mr. Schreiber cites an instance where manufacturers can save in the use of standard patterns. I will cite another instance that came under my own supervision. A certain mining company attempted to build a surface plant from a manufacturer's drawings. The first thing I discovered upon arrival in the field was, there were three different gauges of tracks. The manufacturer's representatives who supplied the cars admitted to me that he called for the different gauges because he had standard patterns for the cars, which he did not want to alter. On the whole, I think that each engineer has his field of usefulness. A company that attempts to build from manufacturers' drawings makes a mistake. A chief engineer who is bigoted may prove an expense to the mining company. The broad-minded chief engineer, who has studied the standards of manufacture, who knows how to specify what is wanted, and who knows how to design the special thing, will prove a valuable adjunct to any mine.

MAX J. WELCH.

Los Angeles, May 24.

Valuation of Mining Stocks.

The Editor:

Sir—From time to time articles and discussions have appeared in your valuable columns regarding mining stocks, with the evident purpose of finding some method of arriving at the value of mining shares, in order to safeguard investors against loss. The writer feels that in all these discussions it is beyond the mining engineer or critic to safely give advice. It cannot be disputed that every investment in mining prospects is bottomed upon no safe premise or conclusion, but is made rather in the fond hope that such investment may prove to be one of those rare ones where fabulous returns will follow. There is no possible means to judge the value of a mining prospect. You accept it by faith or you do not accept it at all. This deduction is based on the assumption that titles are good, capitalization ample, division of promotion or property interest on one hand and of treasury allotment on the other, reasonable; the management experienced, honest, intelligent, and energetic. The remaining questions relate to the method of raising the needed funds and to the price of stock offered. When stock of a mining company is offered for subscription at, say, 10c. to 25c. per share for the treasury issue, no reasonable purchaser should conclude that the company pretends that the value of the mine warrants it, or that the stock is at that time worth the sum asked. It simply

means that the needs of the mine require certain sums of money for development and equipment. It means that the first offering, in the wholly unproven state of the property, at say 10c., and a second block later at 25, and perhaps a third offering at 50c. per share, will raise the funds required, and that when these sums of money are intelligently and honestly applied, the management hopes (I say hopes) that the mine will be worth a sum of money based upon the highest price paid, multiplied by the total outstanding shares. The trend of argument has heretofore seemed to make it appear that the company or its agent represents the stock to be worth the price asked. By no means is this true in the case of a prospect. You cannot apply stock exchange argument and stock exchange rules in such a case. The whole enterprise at first is a simple venture based largely on faith. Who would maintain that the first 100 shares of a newly organized oil company which realized for development purposes but \$10, made the then outstanding issue of, say, 500,100 shares of the total 1,000,000 capitalization worth a total of \$50,010? That \$10 is their total moving, active, working capital. Suppose no more can be sold. With no derricks erected, no wells bored, and only a location near to some proved oil-field, neither the enterprise nor the stock can have any definite or fixed value. The first block of stock sold is not, in expectancy, as desirable as the second placed, and none of them equals in expectancy the final block placed, for without the final sum the enterprise fails entirely. This is why a board of directors fixes in advance the price at which their different blocks of stock shall be sold. A mining or an oil proposition in the early development stage can have no determined, proved value. It is a matter almost wholly of expectation, and with the same given facts expectation of future development varies with the temperament of each investor. One may say, 'I believe the returns will be 1000%', another, '10% profit yearly', and so on. If there were no promotion stock, if each one bought his stock alike, it would be wholly immaterial whether they paid 10c. or \$1 per share. The less they paid per share, the more shares there would be outstanding to participate; the more they paid, the less to participate. Whatever they paid, if a uniform sum, is in the nature of a voluntary level assessment, the stock in such a case being taken merely to fix their relative interests in expected profits. Let us get away from all this talk about stock in speculative ventures, like prospects and oil exploitation being worth the price asked by the company for its treasury offering. Custom has made it fashionable to incorporate companies high and sell their stock low, simply to conform to a general weakness in human nature which demands higher quotations. All this is founded on fallacy. It is impossible to keep any quotation stable, even in a fully developed producing property. As a prospect has no production, the owner can draw on no showing in fixing an asking price, so he bases the offering wholly on the needs of the property, and the investor should judge it from its expectation and promise. The stock exchange rule cannot apply to a mine while it is young. Its value is almost wholly problematic, and

no two people would arrive at the same conclusion. There is a distinct line of difference between a going enterprise and one in the process of development. The value of the first, and its stock, can be somewhat accurately determined, but no human wisdom can fix in advance that of the second. Buy stock in a developed enterprise and pay for it on its showing. In an undeveloped enterprise, get at the facts, then figure out, in your own way, its reasonable expectation, make your investment or leave it—and win or lose like a man.

J. L. MAKEEVER.

Sintering at Cerro de Pasco.

The Editor:

Sir—The sintering plant at La Fundición, Peru, is of the down-draft type, designed by Frank Klepetko. Shallow pans, with bottoms of steel grate-bars, were first covered with a layer of limestone. Ore was spread on top of the limestone. Hot coals were thrown on the ore, an adjustable hood fitted to the pan, and the air-blast turned on. Sintering here has proved a failure. About three-fourths of the sulphur in the ore was expelled and only about half the fine ore agglomerated. We were thus obtaining a rather inferior product for the blast-furnaces, and losing a large proportion of our available fuel (sulphur). At the same time our labor and coal-costs were high. The treatment of the fine ore in reverberatory furnaces has proved far more economical and satisfactory at the plant. Consequently, the sintering plant has been abandoned. The sintering of fine ore was suspended here shortly after my arrival at La Fundición.

H. W. ROSS.

La Fundición, Peru, May 6.

Crucible Assays.

The Editor:

Sir—When first obliged to teach a beginning class assaying, the writer was impressed by the vague and unscientific discussions of crucible charges as given in the older text-books. Most of them merely give tables of charges for various pure gangues, and it is difficult from these to flux complex mixtures of minerals. A method of calculating crucible charges was therefore worked out, so as to eliminate all uncertainties except the exact percentage composition of the gangue. Professor Fulton's* recent book has a good discussion of the nature of assay slag, but it gives no simple method of calculating charges. It may be of interest, therefore, to present the following directions for crucible assaying, which are given to the students of the University of Arkansas after they have determined a few slags by metallurgical methods: (1) Examine the material submitted for assay and estimate its approximate mineralogical composition. Then write down the corresponding weight of each mineral in the quantity to be melted (usually 0.5 A.T., called 15 gm.). (2) Silica. Add, if necessary, enough silica to make, with that already present in the ore, 2 gm. SiO_2 for each gram of

*'A Manual of Fire Assaying', by Charles H. Fulton.

CaCO_3 , MgCO_3 , or BaSO_4 present, and $1\frac{1}{2}$ gm. for each gram of Fe_2O_3 , ZnO , clay, or other infusible silicate present. Limonite is equivalent to seven-eighths of its weight, Fe_2O_3 and pyrite to two-thirds. Consider $1\frac{1}{4}$ gm. of powdered glass equivalent to one gram of silica. (3) Borax. Add $\frac{1}{3}$ gm. of borax glass for each gram of silica or infusible silicate (clay or tale) present in the ore and the fluxes. For cupel assays add 4 gm. of borax for each gram of bone ash. (4) Soda. Add $1\frac{1}{3}$ gm. of sodium bicarbonate for each gram of SiO_2 present in the ore or fluxes. Consider fusible silicates, as glass, etc., equivalent to 50% silica. For pure lead ores add at least two-thirds the weight of the ore. For clay, tale, etc., use a mixture of soda and potash. (5) Litharge. Add enough litharge (0.20 gm.) to make, with the lead already in the ore, an 18-gm. button, and in addition for the slag 2 gm. of PbO for each gram of silica or infusible silicate in the ore. (Consider glass as equivalent to 50% silica.) For cupels add 2 gm. of PbO for each gram of bone ash. Increase the amount of PbO largely to keep copper, zinc, antimony, arsenic, and tellurium out of the button if they are present in the ore. For ease in correction for silver in the PbO , use litharge in even multiples of 10 gm. only. (6) Argol or nitre. Add enough argol or nitre to make an 18-gm. button. One gram of Fe_2O_3 may be assumed to prevent the reduction of about $1\frac{1}{2}$ gm. of lead, but the reducing power of sulphide should be determined by a preliminary assay, if present. When more nitre than the weight of the ore is required, do not use this method. Roast ores containing much pyrite, antimony, or arsenic, adding charcoal for antimony and arsenic. If but little nitre is required, use the nitre method in preference to roasting. For galena, etc., nails may be used with charges in which the PbO for the slag is replaced by NaHCO_3 in excess. When nitre is added in the nail method, be careful to form no FeO , which will not fuse in the soda slag. (7) Buttons brittle from antimony or zinc, or showing scales of copper, must be scorified.

This system of fluxing forms a bi-silicate of Na_2O and PbO , or $\text{NaPb}(\text{SiO}_3)_2$. This is ample flux for a pure quartz gangue, and in it the other bases dissolve, forming, of course, slags of lower silicates. As given, the charge for pure limestone will yield a slag of an oxygen ratio of 1 in base to 1.54 in acid, not counting the borax. BaSO_4 gives a ratio of 1 to 1.7; MgCO_3 , 1 to 1.47; Fe_2O_3 (as FeO), 1 to 1.33; clay, 1 to 1.42. Since borax is added to form a boro-silicate, it is reasonable to figure it according to the amount of SiO_2 present in the slag. The proportion given has not been finally settled upon as best. It is sufficient to greatly lower the temperature of the slag-formation to make the slag viscous during the reduction period and to lower the temperature of the final complete fluidity. It is also sufficient as a general safeguard to flux a slight excess of either acid or base. On the other hand, it is expensive, and makes the buttons more difficult to clean.

Our charges are a little higher in PbO than usual, and for some basic ores it will be more economical to substitute soda for litharge, but this makes the charge more bulky. For ease in remembering, it was thought better to have a constant ratio of soda and

litharge to silica, rather than to use the form 1 to $1\frac{1}{2}$ gm. soda, $1\frac{1}{2}$ to 2 gm. PbO , for each gram of silica. This is more nearly what would be used by an experienced assayer.

The amount of flux as given by this table is ample. In estimating weights to be fluxed, even grams are taken, using care to see that the weight of refractory mineral is over rather than under-estimated. The minimum amount of the sodium-lead-silicate required to dissolve the various bases has not yet been accurately determined. This should be worked out for the more common minerals by making up charges of the pure oxide. It is also desirable to work out the amount of excess litharge needed for each gram of copper, antimony, etc., in the charge to make clean buttons. This PbO method has been found to work well with as much as 25% antimony and 60% zinc, but it is not so successful for copper. A large excess of PbO severely attacks the crucibles, and the risk of ruining the muffle-button by spilled charges becomes important. Therefore it is thought best to scorify the copper buttons as is done with the buttons obtained in the standard scorification method for copper mattes.

On account of this dissolving action of litharge upon the crucibles, more litharge than that given in the directions is of advantage in assaying clay and tale ores. The charges without excess of litharge have very little effect upon Denver crucibles, and they attack Battersea crucibles but slightly. The borax seems to protect the crucibles from being 'drilled' by PbO , probably by coating them with a viscous aluminum boro-silicate.

I have found that by long fusion cupels can be entirely dissolved to a fairly fluid slag by much borax with some PbO and no soda or silica. This forms calcium borate and sodium phosphate, as in the tests on platinum wire. The amount of bone ash in the charge is determined by weighing the cupel with the litharge and subtracting the standard weight of that size cupel when new in order to give the PbO to be deducted from the weight of the stained part of the cupel. Apology is offered for the incomplete state of these data, but I hope that the chemistry department can again take up instruction in assaying and continue the investigations begun.

A. A. STEEL.

Fayetteville, Arkansas, May 20.

Public interest in the desert region, which comprises an area of about 68,000 square miles, is intense, largely because of the discovery and development within it of mines that are heavy producers of gold. The resources of the desert, however, are not confined to the precious metals, but include many other products of economic value, among which may be mentioned several valuable salts, including borax, soda, gypsum, and common salt; building material, including marble, onyx, brick clays, and cements; baser metals, like copper, iron, and lead; and gems, among which are turquoise and opal. These products are widely distributed throughout the desert. A report, with a map showing water-holes and important roads on the desert has just been issued by the U. S. Geological Survey as Water-Supply Paper No. 224.

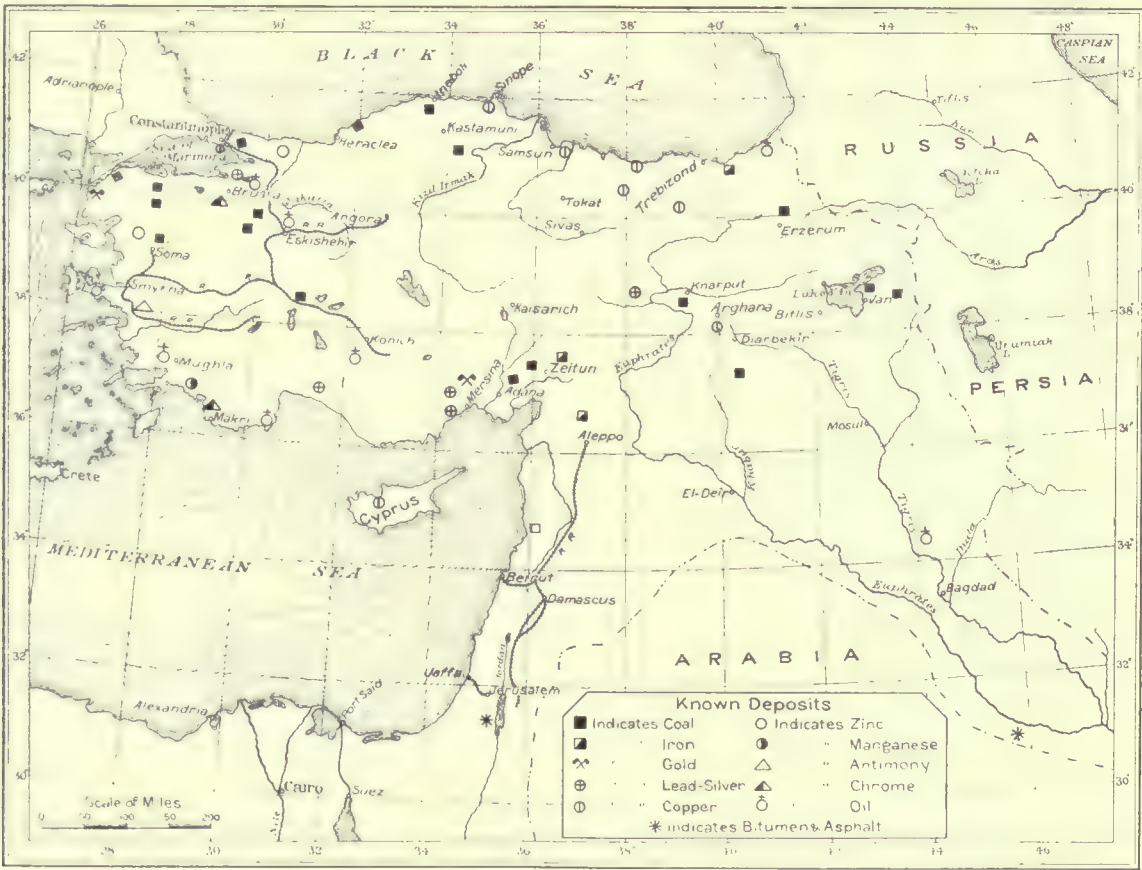

MINERAL RESOURCES OF THE TURKISH EMPIRE.

Written for the MINING AND SCIENTIFIC PRESS
By LEON DOMINIAN.

In an era when the fostering and conservation of a country's natural resources are reckoned among the objects of enlightened administration, it is instructive to note how the lack of such solicitude has checked the advance of the mining industry within the Turkish Empire, the boundaries of which now comprise the richest mining districts known to antiquity. The areas of Europe and of Asia, included within the Sultan's dominions, have been the seat of active mining operations from about 2000 years B. C. to the end of the eleventh century. Subsequent to

posits lie in the folds of the marginal uplifts. Our knowledge of the general geology of the country is exceedingly meagre. Occasional reports from travelers, many of whom were neither geologists nor miners, afford but scant data, and the fragments of reliable information derived from authorities like Tchihatcheff and Spurr are too few to allow generalizations. A splendid field of investigation is undoubtedly open to scientists and technical men.

Any attempt to partition off the map of the country into areas, each of which would include distinct types of ores, irrespective of their mineral contents and with distinction based solely upon the mode of occurrence or genetic nature, would, at the present stage of our knowledge, be useless. Nevertheless, certain minerals are more abundant in some districts

Map Showing Mineral Resources of Asiatic Turkey.

this period, centuries of corruption and misrule barred the development of industry. With few exceptions, all that remains today, consists of innumerable old workings scattered throughout the Empire. Turkey in Asia, especially, abounds in mineral wealth. A glance at the accompanying map suffices to reveal the fact that Asia Minor is abundantly mineralized.

An interesting relation between orographic features and the occurrences of mineral deposits is observable. The westernmost projection of the Asiatic continent may be likened to a bowl, the rim of which is partly formed by the coastal mountain chains, the rest being completed by the elevated ranges of eastern Armenia, along the Russian and Persian borders. The interior of the bowl is made up of the plateaus which, so far, are not known to be extensively mineralized. At all events, the bulk of the known ore de-

than in others. Moreover, an oil-belt has already been recognized by J. E. Spurr. That able mining geologist states¹: "Oil will probably be found in a general belt which runs southeastward from the eastern part of Armenia on the Black Sea down to the Persian Gulf." Beyond this assumption, with which the writer fully concurs, none but differentiations along similarly broad lines should be attempted at present. The following description will accordingly be confined to an enumeration of the minerals known to occur, with a mention of the localities wherein they exist.

Coal.—The Heraclea coalfield is at present the best developed in Turkey. It occupies a belt about 60 km. in length, along the Asiatic coast of the Black Sea, between the seaports of Heraclea and Filios. The town of Heraclea itself lies at a distance of 135

¹Eng. & Min. Jour., Oct. 4, 1902.

nautical miles from Constantinople. The coal-beds outcrop near the coast and are not known to extend farther than 8 km. inland. It is believed, however, that they strike southeasterly from the eastern boundary of the district, to which mining operations have been confined, and that they may be re-encountered at a greater distance from the sea-shore beyond. The coast is precipitous and mountainous. The topography is rugged. Narrow valleys and ridges parallel each other at right angles to the shore-line. The coal-measures overlies Carboniferous limestones and are in turn unconformably overlaid by Cretaceous beds of great thickness.

A study of the fossil flora has led to the division of the measures into three series or stages corresponding the Culm, Westphalian, and Stephanian subdivisions of the Carboniferous period in Europe. These are respectively the Aladja-Azy or lower stage, the Cozlou or middle stage, and the Caradon or upper stage. The first two are economically the most important, but the best coal is derived from the middle stage. The entire region has been considerably disturbed by repeated faulting subsequent to the formation of the coal. The veins have a general east-west strike, and dip between 10° and 30° to the south. At certain points, however, the dip is northerly. Again, at Tsamly, vertical seams have been worked.² The coal is an excellent type of bituminous, though slightly higher in ash than the corresponding average type from European basins. In this it resembles the Cretaceous product of the Rocky Mountains. It may be divided into two classes: (1) obtained from the veins of the middle series containing from 30 to 40% volatile matter; (2) mined from the lowest stage, containing from 40 to 45% volatile matter. The first is excellent for coking purposes, while the Aladja-Azy product is used chiefly in the manufacture of illuminating gas and for steam generation. The whole region has been held as private property by the lately dethroned Sultan. It is probable, however, that one of the results of his dethronement will consist in the restoration of these deposits to the State, and that concessions will then be granted in compliance with the provisions of the mining laws of the Empire. The district was hitherto worked under special regulations which had nothing in common with these laws. The right of exploitation was granted to Ottoman subjects alone, although transfer could be made to foreigners with the sanction of the Government. Working permits covering circular claims of a diameter of 450 metres could be obtained upon application, the centre being taken at the point where operations were actually started. The grantees could dispose of only 40% of the output, the balance having to be held at the disposal of the Government at a price settled beforehand. This balance, however, could be sold otherwise, in case the Government signified its unwillingness to purchase. Furthermore, 10% of the fine passing through screens with 1 cm. apertures, belonged to the Government. In case a mine was not worked during three successive months it reverted to the Sultan. A fixed charge of 5 piasters (\$0.22), called the *foncional*, was col-

lected on every ton shipped. This tax could be paid in kind.

As a rule the mines were opened by means of two or more main slopes at a distance of from 50 to 100 metres apart. Transverse entries, driven along the strike of the veins, subsequently connected the slopes, and were in turn connected with each other by a system of galleries driven every 25 metres. Development proceeded until, as has happened in almost every instance, the vein was cut off by a fault. Then mining was begun, the coal being attacked at the breast of the galleries first. Work was conducted backward, the caving system being applied as the coal was won while the miners receded toward daylight. Half-ton cars running on 60-cm. gauge tracks, were used for tramping the product, although in the narrower galleries, the coal was handled on men's backs in 25 kg. loads. The men worked on the system of day's pay or by the task. The Société d'Héraclée, a French company, and the most important in the district, at first paid wages by the day, but subsequently adopted a straight leasing system. Owing to the waste incurred through negligence on the part of the lessees, this was abandoned and replaced by task-work entirely.

By far the largest proportion of the output is hauled over the French company's narrow-gauge railway to Zoungouldak harbor, where cranes of 4 tons capacity, capable of handling 3000 tons in 24 hours, discharge directly into the holds of vessels. The mines at Tehatal-Azy are connected by an aerial tramway to the Usulmez railway station. The output from all the mines during 1907 amounted to 625,000 tons. During 1908 about 200,000 tons was consumed in Constantinople alone. About 100,000 tons is shipped annually to various important points, such as Smyrna, Bourgas, and Galatz. Over one-half of the annual production is sold at Zoungouldak to steamers that call there to coal. The ton-cost of the product, laid on the wharf, is stated to be \$1.45, out of which 88c. is charged to mining. The freight rate to Constantinople is \$1.20 per ton. During 1907, 20,000 tons of coke was produced from two batteries of 50 coke-ovens of the Coppée-Bernard system. A large portion of this coke is sold to the Laurium smelters in Greece, the balance finding its way to Marseilles.

In addition to the Heraclaea basin, coal-beds are extensively distributed, both in European and Asiatic Turkey. Lignite appears to be abundant throughout the European provinces of the Empire. At Dedeagatch, Soufli, Ouzoun-Keupru, and Keshan, all in the Province of Adrianople, several beds of lignite coal have been opened, and it is claimed that exploration has led to satisfactory development at the last named point. Lignite is also reported from the vicinity of the seaport of Rodosto on the Sea of Marmora. Prospecting for coal has been done in the neighborhood of Grison-Assar, at a distance of three hours from Xanthi's railway station. Farther west thick seams of lignitic coal have been discovered in the Provinces of Salonica and Monastir. In Albania a fair quality of coal has been mined near the towns of Telvino and Triano. Deposits of lignite are also

²S. Stassinopoulos. Bull. Cham. Com. Franc., Oct. 1908.

known near the villages of Akbrunar, Tchiflik, and Aghatchly at a short distance from Constantinople.

Passing to Asia Minor, it appears that the north-western portion of the peninsula also contains seams of lignitic coal. These, in all probability, can be correlated with the European beds. Indeed, 40 years ago, the Russian geologist, Tchihatcheff, called attention to the fact that the European and Asiatic provinces immediately bordering the intervening seas constituted a single geological province. In the neighborhood of Ismid and farther west at Lamp-sacus, lignite beds have been found, but, to date, they have not been largely exploited. At Manjilik, however, in the extreme northwest of the peninsula, there is a lignite mine where thick seams outcrop for a length of $2\frac{1}{2}$ miles. This deposit is worked by the Société Anonyme Ottomane, owning the near-by lead mines of Balia. The product is used as fuel for an electric-power station feeding the lead mines. Farther south, a short distance from Soma, the terminal of a branch line from Manissa, a good quality of lignite has been mined on a small scale. Southwest of Tchali railway station, between the towns of Kara-Hissar and Ak-chehir, a $6\frac{1}{2}$ -ft. seam of hard coal has been uncovered. At Kuré, between the railway stations of Eskichehir and Bilejik good thick seams of lignite are worked. Near Adana, in southeastern Asia Minor, are veins of bituminous coal. Explorers have also noted fragments of anthracite in the vicinity of the ancient town of Sis. In the Province of Beyrut two relatively important deposits of lignite are worked. One lies near the village of Kermael and yields about 1000 tons annually. The other occurs in the valley of the Nar-el-Kalb and produces about 500 tons per year. It is claimed, however, that both deposits are capable of a larger output.

North of the Arabian desert, in the Provinces of Diarbekir and Memouret-ul-Aziz, all grades of coal from lignite to anthracite are reported. Anthracite is also reported from the neighborhood of the town of Harput, as well as from deposits discovered between Lake Van and the Persian border. The probable existence of an anthracite basin in this vicinity is further corroborated by discoveries of high-grade coal near the town of Palou and at Tehinvich-Kezek, not far from the Euphrates river. At about 50 km. northwest of the town of Erzeroum, a lignite mine yielded 100 tons in 1900, and has since been worked on a small scale by the municipality. In the Province of Castamuni, along the Black Sea coast, what is claimed to be an important field has been discovered at Bije near Amasra. At 18 hours distance from the town of Ineboli, as well as at various near-by points, anthracite is found.

Iron. Little is known regarding the occurrence of iron-ores within the Turkish Empire. In the Province of Trebizond, blacksmiths melt in a crude fashion certain ores obviously derived from neighboring localities. The product is used in the manufacture of implements of daily usage. The Zeitun district, at the foot of the eastern slope of the Anti-Taurus mountains, in southeastern Asia Minor, is said to contain extensive deposits of high-grade iron-ores, and it is known that blacksmiths throughout

Syria and Mesopotamia obtain their iron from the natives working these deposits. Iron mines are also worked in the vicinity of Aleppo. In western Asia Minor iron-ores have been discovered at Vierla and Bazarkeui. In European Turkey there exists a deposit at Gumuljina in the Province of Adrianople.

Gold.—About 1500 fine ounces of gold is produced annually in Turkey. In the Kardagh mountains of Macedonia the natives wash auriferous gravels along the banks of the rivers. Gold-ores are known to occur along the Asiatic coast in the vicinity of the Dardanelles, and gold-bearing quartz veins have been discovered in the Bulgardagh mountains in south-eastern Asia Minor. There is no reason why this precious metal should not be eventually recovered as a by-product in the extraction of other ores. It will probably be found to occur associated with copper and argentiferous lead-ores, thereby substantially increasing the future production.

Lead and Silver.—The best developed silver-lead mines are in the Province of Hudavendighiar, near the town of Balia, at a distance of about 100 km. from the sea. The ore occurs in a contact-zone between Tertiary augite-andesite and Carboniferous limestone. The contact-zone varies between 6 and 16 ft. in width. The limestone at the contact is silicified but barren. In the andesite, on the other hand, are found accumulations of pure galena which seem to be connected with fissures parallel to the contact-zone.³ The ores carry galena, blende, and pyrite, and contain on an average from 16 to 20% lead and 8% zinc.⁴ The plant at Balia comprises a mill of 400 tons daily capacity for the production of lead concentrate, and a Wetherill magnetic separator for making a blende product. The smelting works are provided with a water-jacket lead-furnace of rectangular section, 1 by 1.8 metres, of 100 tons daily capacity. The slags produced contain 20% Pb, 20 gm. Ag, and 10% Zn per ton. In 1903, the mine output amounted to 63,000 tons, yielding 7600 tons of pig lead, with an average content of 97.5% Pb and 1950 gm. Ag per ton. The pig lead is transported to the coast, whence it is shipped to Frankfort in Germany for refining. Besides the lead product, about 2000 tons of zinc concentrate, assaying 41% Zn is produced annually. The company owns and operates the lignite mines at Manjilik described above. Here an electric-power station has been installed. Generators having a total capacity of 700 hp. produce the current, which is transmitted to Balia and the mines. The average cost of current per kilowatt-hour is 0.09 fr. (\$0.017). The smelting costs, including preliminary roasting, are about 60 fr. (\$11.40) per ton of ore treated. Milling costs amount to 3.8 fr. (\$0.72) per ton.

South of Kurnasti two deposits of silver-lead ores are known, at Dumbeltek and Keskdere. An inspection of the abandoned workings at this point reveals geological conditions similar to those observable at Balia. Sixty-five kilometres north of Mersina, in the Taurus mountains, a silver-lead mine at Bulgar

³K. E. Weiss. *Zeit. f. Prak. Geol.*, 1901.

⁴G. Ralli. 'Lead Mines of Balia,' *Eng. & Min. Jour.*, Feb. 18, 1904.

Maden has been worked by the Government. Lack of fuel, and heavy transportation charges to the coast, added to ignorance of mine exploitation methods, prevented profits being made. During recent years little work was done at this mine. About 25 km. northwest of Soma there exists a district from which, according to reports, galena float has been found in association with blende and chalcopyrite. In Turkey in Europe, I have, not infrequently, found galena 'float' in the ravines of Bebek and Rumeli-Hissar along the shores of the Bosphorus. Owing to a variety of causes no attempt was ever made to trace the 'float' back to its source. At Kratova, in Macedonia, old workings in a deposit of argentiferous lead have been unearthed, and it is reported that a British company is about to undertake development.

Copper.—Copper was mined in the vicinity of Constantinople. The island of Halki (a corruption of the Greek word 'Kalkos' meaning copper), lying at the western entrance to the Bosphorus, contains numerous old workings, now mostly caved in. Appreciable quantities of pyrite and chalcopyrite are exposed throughout the island. A similar deposit, on which a little work has been done within the past 50 years, is known at Sariyari on the northeastern shore of the Bosphorus. Farther west, in the vicinity of Rumeli-Hissar, a copper vein has been reported. These occurrences are found along well defined contact-zones between eruptives and limestone. In Asia Minor the existence of a rich copper belt along the eastern portion of the Black Sea coast is suspected. Six different properties are now being operated in the vicinity of the sea-port of Sinope. At Espie, near Kerasunde, important exploration is being conducted on a copper concession thickly studded with old workings. High-grade copper ore is also reported from the vicinity of the towns of Gumushane and Karahissar. In the neighborhood of Trebizond, a number of copper mines are being worked on a small scale. It is interesting to note that this region was the very one which gave origin to the ancient mythical tales referring to the Golden Fleece, fabulous reports of untold wealth to be found on these shores being spread by the early navigators. The celebrated Argana mines are almost due south of the eastern border of the last named district, at the source of the Tigris river. From all accounts very high-grade ore is mined at this point within an area of 12 km. square. The deposit is known to have been exploited since the year 1096 A. D. During recent years, operations have been carried on intermittently by the Government, both on a leasing system and by direct management. Cuinet gives the following analysis of this ore: Cu 30%, Fe 40%, S 30%. Weed⁶ states that the ore is high-grade, carrying from 10 to 12% Cu. Mining is conducted in the most primitive fashion. The ore is broken to nut size, conical heaps of the broken material are built and covered with wood to which fire is set. This roasting lasts three days, and is succeeded by a similar operation on the product of the first roast. The resulting matte, containing

25 to 30% copper, is smelted in closed kilns from which the 'black copper', as it is known to the trade, is finally derived. All of this black copper is transported on camel-back to Tokat, where it is refined and subsequently shipped to the sea-port of Alexandretta. The cost of mining and smelting is estimated at less than 3c. per pound, this being the price paid by the Government, which, so far, has reserved for itself the sole right of purchasing the mattes. Transportation from Tokat to Alexandretta costs 2c. per pound. At the time of writing it was learned that the Government had decided to turn over the mines to private parties. Deposits of copper are also known at Baibour near Honlay as well as at Haire and Bulbuldere.

Zinc.—A deposit of calamine is worked at Karasu, close to the Zakaria river, in the Province of Ismid. The mines are owned by a French company. Other known deposits of zinc ore in the Provinces of Salonica and Adana have not yet been developed. A small amount of work has been done on a zinc mine at Bazar, in the district of Bigha. Zinc has also been discovered at Kirasliyal, in the vicinity of the ancient town of Pergamos.

Manganese.—Two important districts produce manganese ores in Turkey. These are the Kassandra district, in the Province of Salonica, and the Phlinika district in Asia Minor. The ore occurs in both places in the form of pyrolusite, the Asiatic variety assaying 52% Mn. A small amount is also mined at the Zengani mines, with average assays showing 83% manganese dioxide. Manganese mines are also worked in the Province of Trebizond. Occurrences of these ores are, moreover, known in the vicinity of the sea-port of Moudania, as well as near Seshkeui, Balia, and Ushak, all in Asia Minor.

Antimony.—Stibnite has been found in the Provinces of Adrianople and Monastir. Near Rozdan, the ore occurs in a clay gangue at a contact between schist and dolomite. Considerable work has been done here. The ore is concentrated on the spot to about 55% antimony, and is then shipped to European points. Other localities where stibnite is found are the islands of Mitylene and Chios in the Archipelago. Some development work has been done on the former, but no attempt has been made to establish a steady production. In Asia Minor most of the deposits are found in the Province of Aidin, whence shipment is made chiefly to England by way of Smyrna. The two important centres of production in this Province are Eudumish and Djinli Kaya, in both of which high-grade ore is found, often carrying as much as 65% antimony. At the last mentioned point the veins occur cutting through crystalline schist. The Gomekehiflik mine lies on the southwest slope of Kisil mountain. This mine has been leased for 13 years to Greek contractors on a royalty basis.⁷ About 100 men are employed during nine months of the year, the output for that period averaging 500 tons of sorted ore. Other deposits are known at Demirkapou, Sulukeui, and Ivrendi, all in western Asia Minor.

Arsenic.—The Turkish mines yield about 3000 tons

⁶Vital Cuinet, *Turquie d'Asie*, Vol. 2, p. 481.

⁷*The Copper Mines of the World*, by W. H. Weed.

⁸K. E. Weiss. Loc. Cit.

of orpiment annually. This mineral is usually found associated with antimony. The mines at Elkhur, near Rozdan, produce 500 tons per annum. The ore is found in the same veins that carry the stibnite, but in pockets free from the presence of this last named mineral. Most of the product is shipped by way of Salonica to France, a small proportion being reserved for home consumption. The mines near Yenikeny are important. They are noted for the excellent quality of their ores, which run as high as 42% arsenic. Some gold is present. About 1000 tons of this ore is shipped every year to Europe. Orpiment mines also exist at Togan-Hissar, near Dedeagatch, in the Province of Adrianople and at Eyriden, in the Province of Salonica. Arsenical pyrite has, furthermore, been found in the Endumish deposit described above.

Chrome.—Turkey has contributed largely to the world's supply of chrome ore. The Turkish ores are soft, rich in chromic oxide, have a low silica content, and are free from objectionable impurities. In European Turkey some mines are worked near Salonica, the ore from which assays between 48 and 52% chromic oxide. The principal districts are those of Kamene and Roshdan. In Asia Minor the mineral is of widespread occurrence throughout the west. It must be stated, however, that the production has fallen off in recent years. The most important mines were those of Dagardy, south of Mount Olympus, in the Province of Hudavendighiar. From estimates made in the course of the year 1900, the existence of an orebody in this locality, measuring 120,000 cu. ft., and containing 50 to 56% ore was surmised. Another important district was that of the basin of Maeri, of which the seaport of that name facing Rhodes Island, was the chief point of shipment.

Asphalt and Bitumen.—Asphalt springs are known at Polina, near Durazzo, in Albania, also at Avlona in the same province. A small amount of work has been done at this last point, whence the output was shipped to Trieste. The most important bitumen field known lies in the region formerly called Judea, in Asia Minor, which now constitutes the Provinces of Aleppo and Syria. As far as can be gathered from available statistics the production during the past 20 years has averaged 10,000 tons annually. Starting from the southern extremity of the Dead Sea to the source of the river Jordan, the deposits lie along an axis parallel to that of the basin. They occur as impregnations in a Cretaceous limestone. The most extensive of all is the one at Nebi-Musa which reveals itself on the surface in large bluish patches. That of Hasbeya, at the northern extremity of the Jordan, is analogous to the former, but not as rich. At the time of the Egyptian conquest Hasbeya was the seat of regular working, and the remains of some twenty pits can still be seen. Bituminous springs have also been found opposite the town of Nasarieh in the Province of Basra.

Petroleum.—The district around Bagdad, in the southeastern portion of Turkey may acquire importance as an oilfield. Around Cherizor the natives sink pits in order to collect the greasy liquid which seeps through the loosely consolidated rocks. As a matter of fact, oil seepages have been traced all along

the Iranian mountains from Erbil to the Persian Gulf. In northeastern Armenia indications are not wanting that the Baku oilfields continue into Turkish territory. On the southwestern coast of Asia Minor, north of Cape Chaledonia, gases are continually escaping from fissures in a peridotite rock intruded in limestone. This phenomenon has been observed for 2800 years, and may have economic significance, as it has been recognized that the escape of gases are usually associated with oil. Indications of oil have also been found in the vicinity of Lake Isnik in the sea of Marmora basin.

Borax.—Extensive beds of pandermite, a massive and not entirely pure variety of colemanite, a calcium borate, are mined at Sultan-Tehair, in the Province of Hudavendighiar. The mines lie on the mail-route leading from Panderma harbor to Balikesser. According to Weiss the pandermite occurs in Tertiary sedimentaries lying in a basin surrounded by steep hills of gabbro, granite, and crystalline schist. The productive bed consists of a brownish to bluish gray gypsum, containing nodules of variable sizes dispersed within the gypsum, and forming from 10 to 20% of the aggregate mass.

Lithographic Stone.—This substance occurs in extensive massive beds north of Mihailich, also east of Kimashti, and south of Abulonia lake.

Emery.—The production of emery from Asia Minor and the islands of the Aegean sea practically constitute the bulk of the world's supply. The output of the former exceeds that of the latter. The mines lie in a belt extending 200 miles south and southeast of Smyrna. Noteworthy localities are Cozburnar and Azizie on the Aidin railway, 50 miles south of Smyrna. The ore is found in lumps up to 5 in. diam., embedded in a red-brown clay, and associated with fragments of calcite. Other producing localities in this district are Hassan-Chauslar and Soka. The cost of production at the mines is estimated at \$8 per ton. About 60% of the total production is shipped to the United States.

Meerschaum.—The plains near Eski-shehir, in Asia Minor, constitute one of the important localities from which this hydrous silicate of magnesium is mined. The meerschaum district extends from the town of Eski-shehir, on the Anatolian railway, almost due eastward to the city of Angora. The mines lie at a distance of about 22 km. from the railroad station, to which the ore is packed by camel trains. The two chief producing mines are those of Saresu and Sepki. The deposits occur in a valley filled with drift material from the surrounding mountains. The sepiolite is scattered through the drift in rounded nodular masses with fragments of magnesian and hornblende rocks. As a rule the nodules do not exceed 3 in. diam., but a few attain larger dimensions. In the raw condition the mineral is soft, light, and non-transparent. The color is white, with occasional blending of yellow, red, or gray. It is richer in silica than that found in Utah and North Carolina. The thickness of the meerschaum-bearing strata varies between 10 and 130 ft. Mining is carried on by means of the leasing system, both in open-cut and underground work.

Mercury.—Two deposits of cinnabar are worked at present in Asia Minor. The Karabournou mines, situated about 30 km. from the town of Smyrna, produce about 3000 flasks annually. The deposit lies in the vicinity of basaltic flows, and consists of metamorphic silicious schist impregnated with cinnabar.⁸ Mining is done entirely in open-cuts on ores containing as little as 0.25% Hg. When sorted the cinnabar appears to concentrate in the fine, and the ore is accordingly screened. The concentrate assays from 0.75 to 2% Hg. The plant at the mine comprises two double Spirek tower-furnaces for broken ore, and a Cermak-Spirek furnace for fine. This installation has a capacity of 30 tons per day. The other deposit occurs in the vicinity of Konia in Asia Minor.⁹ Here the ore is found in veinlets, nodules, and small particles, in a crystalline limestone close to schist, at no great distance from old eruptives. The mineral appears to be present wherever the limestone becomes silicified. Some stibnite is associated with the cinnabar. Up to the middle of the year 1905 about 15,000 tons of 1% Hg had been opened up.

The foregoing review should not be considered merely in the light of a retrospective survey, but rather from the standpoint of future development. That a good deal of mining has been done to date, despite extremely adverse conditions, is a good portent. It is highly probable that copper mining and smelting will be carried on extensively along the eastern Asiatic coast of the Black Sea down to the sources of the Tigris and of the Euphrates rivers. There is also promise of a rich oil belt in the vicinity of, and running parallel to, the Russian and Persian frontiers. The development of a thriving coal and coke industry in Asia Minor is a possibility within easy reach of capital and energy. The Macedonian provinces are already known to contain a variety of minerals, and must necessarily become the seat of active mining camps. The same can be stated of western Anatolia. Flourishing industries, however, are perforce subordinate to the existence of order and peace. Fortunately, there is reason to believe that the men at the head of the present administration intend to carry out a broad-minded policy that will favor the expansion of mining and its allied industries. With the adoption of such a course, many interesting features of technical practice in Turkish territory will doubtless be revealed within the next decade or so. Most mining engineers are familiar with the admirable results obtained in Mexico, within a comparatively short period of time; nor is the result of push and energy in our own Far West less striking.

Comparisons are instructive at times, and it were futile to belittle the importance of granting due recognition to modern industrial tendencies as exhibited in the practice of the more advanced nations. A study of these features and the causes conducive thereto may advantageously shape the policy to be adopted by those upon whom the responsibility of developing a country's natural resources has been thrust.

GEOLOGY OF THE PLATINUM DEPOSITS OF COLOMBIA.

Written for the MINING AND SCIENTIFIC PRESS
By J. CICERÓN CASTILLO.

On the west slope of the Andes, in the Republic of Colombia, is being developed an enterprise with a solid future. This is contemporary with the new San Francisco, since, by a singular coincidence, it has been developed within the same epoch that the fallen city has lifted itself from the ashes. In April, 1906, G. H. Nisbet sailed from San Francisco to Buena Ventura, a port on the Pacific coast of Colombia, to superintend the work. Mr. Nisbet had just returned from Russia, and was especially familiar with platinum deposits, and it was for this reason that he was selected to explore the only known deposits of platinum on this continent. These alluvial treasures, which will soon be exploited on a large scale, will within a short time become the scene of dredging operations. Keeping step with the investigation of the economic side of the problem, the petrology has also been studied in the mountains. It occurred to the author to make a geological excursion in search of the origin of the alluvial platinum, which constitutes one of the great and peculiar riches of Colombia. In this particular case the float now gathered as gravel into the streams was not of the character which usually accompanies the gold in that region, but revealed a series of unusual rocks. The San Juan valley, famous for its auriferous gravels in its upper part, was the most notable mining centre in Colombia in the Colonial epoch, and was known as the Chocó, which has been described to the world by Baron Von Humboldt. History assigns a production of \$600,000,000 to this region from the sixteenth century to the end of slavery in the past century. Five thousand negroes were transported by the Spaniards directly from Africa, and the descendants from these constitute today 75% of the population of the Province. It is not the object of this article to give an account of the days of Spanish gold mining, which in their magnitude are comparable only to those of California, but it is desirable to record that, slavery having been terminated, the negroes remained practically the owners of the territory, having continued until the present time on their own account and initiative as workers with *batea* and sluices. These people have no incentive for work, because Nature is so prodigal that want of food is entirely unknown, and there is so little demand for clothing that the breech-cloth is practically the only garment used. Notwithstanding the absence of necessities as an incentive to labor, the annual mineral production of this district as pursued today will not fall below \$300,000 gold, and it is constantly augmenting. The increase in the price of platinum was directly responsible for the growth of mineral exports from the Province of San Juan. During the Colonial epoch platinum had little or no use in the arts. The Spaniards cast it aside as one of the 'impurities' encountered in their mining for gold. The river Condoto, which is today almost the sole producer of platinum, contains very little gold, and the platinum in these

⁸ F. P. Monaldi. *Rassegna Mineraria*, April 11, 1908.

⁹ F. P. Sharpe. *Eng. & Min. Jour.*, Sept. 26, 1908.

gravels greatly disturbed the early miners. The Condoto accordingly escaped being worked by the Spanish miner of those times, and its alluvial deposits are practically intact. The workings of the last 10 years have been more in the nature of prospecting made by the natives in search of easy riches, and it is surprising how that multitude of workings here and there, after having yielded in places two or more dollars per cubic yard, is still valuable as a basis for operations by a company which has obtained possession of the river and its dredgeable gravels.

In order that the reader may better understand the conditions, it is desirable to call attention to the map which accompanies this article, showing the geographical position of the gold and platinum deposits. A north and south depression, due to geological

Map of the Chocó, Colombia.

causes and not to erosion, almost results in a union of the Atrato and San Juan valleys. This depression was evidently formed before the Tertiary era, and there is evidence that it connected the Atlantic with the Pacific ocean prior to an uplift, which evidently occurred during or after the Cretaceous period. The origin of the platinum is to be found in the eruptions which occurred subsequent to that period, as is evidenced by the character of the gravels accompanying it. The geological evidences at present available point to an overflow of rhyolites and trachytes, which cover the western slopes of the Western Cordillera of the Colombian Andes. This was of exceptional duration, and buried the ancient andesitic formation under thousands of feet of Tertiary lavas. These were exposed in a later epoch by erosion which has cut deep valleys, following the volcanic activity referred to. The lava covered practically the entire surface throughout this region, which constitutes

the hydrographic basin of the San Juan river, the only portion of the country which the author has had an opportunity to study. The rapidity of the cooling of these volcanic rocks is evidenced by the absence of crystallization in the Tertiary rocks. No obsidian, however, has been discovered in the district. The rapid cooling referred to produced an incalculable number of shrinkage cracks, which were subsequently filled by gold-bearing quartz deposited from hydro-thermal solutions. The platiniferous rocks are actually intrusions, and their appearance on the surface of the earth at this point was subsequent to the formation of Tertiary lavas, through which it was injected after the gold had already been deposited along with the quartz. As a result of these intrusions, the opportunities for carving out new water-courses by erosion were multiplied. These cut the orographic axis of the Cordillera and add many affluents to the river San Juan.

A great flood period, comparable to the Châmpplain, has displayed itself since the final volcanic activity, and the conditions which it produced, and which to a considerable extent are paralleled today, have contributed, even down to the present time, to the enormous work of cutting down the rocks with their precious-metal contents and forming the first alluvial deposits. Many of the gravels have been transported great distances, and many of the original deposits have been eroded a second time, resulting in concentration, which has produced in certain cases fabulous riches. These frequent changes have resulted in leaving great areas of gravels without any soil covering, so that they are available for dredging. It only remains to add that subsequent volcanic eruptions of a local character have occurred within recent epochs, which have left their mark written in the material of the alluvial deposits, demonstrating, as in the valley of the San Juan, which today empties into the Pacific, that it formerly discharged its waters into the Atlantic, and that these changes in direction occurred apparently several times. There are indications that even the tides may have affected this region, and may have flowed across from what is now the valley of the San Juan into the valley of the Atrato.

The mother rock of the platinum in Colombia is a volcanic in which pyroxene predominates, together with feldspars. It is a quite typical gabbro. The rock in which the author has had the fortune to find platinum is found in characteristic dikes, after the manner of veins. It is almost as black as jet, but is made up of a dense mass of pyroxene crystals containing pyrite, in which the platinum occurs in the metallic state. The same rock also shows small quantities of nagyagite.

The basin of the Condoto river is the centre of platinum mining in Colombia. At the present time there are no deposits elsewhere in the world which contain so large a quantity of this metal. It is characteristic of the alluvial deposits of the Condoto that the platinum predominates absolutely above the gold in point of quantity by weight, the platinum constituting from 75 to 80% of the metalliferous content of the samples. Many observations, made by the author, on

these deposits have brought him to the conclusion that the growth of gold particles within these placers by precipitation from solutions has not taken place, but that the metal has been brought by mechanical means exclusively. Each particle of gold, on being broken loose from its quartz gangue, and by the oxidation of the sulphide of iron which imprisons it, loses consecutively a part of its weight. The nuggets, however large they may be, show evidence of having been worn and reduced in size; that the platinum existed originally in the gabbro is a fact which the author has proved. It is present in the same manner as tin oxide (cassiterite) is contained in granite. It is interesting to note that this black gabbro follows the platinum wherever it is found in the upper valley of the San Juan, so that the color of the gravel is at once an indication as to whether it is platinum-bearing or whether it is gold-bearing. The gold-bearing gravels are whitish and reddish in color, while the platinum, owing to the gabbro, have a bluish-black color, which is extremely characteristic.

The separation of the gold from the platinum-bearing gravel is so sharp that it was by this means that the author was able to trace up the platinum to its source. While gold is found, as before stated, in conjunction with the platinum in the gravels, in those which are especially auriferous, no platinum whatever is discovered. The Condoto is at present under control of a company which is having a dredge built by the Risdon Iron Works of San Francisco. This will soon be in operation. At the present time the company is obtaining good returns from washing the platinum-bearing gravels by the old crude methods which have been in vogue for over a hundred years. The author has made extensive tests and has demonstrated the existence of valuable platinum placers through a length of valley of more than 30 miles.

PRECIPITATION OF GOLD BY CARBONACEOUS MATTER.

By W. A. CALDECOTT.

*The fact that gold is precipitated from auriferous cyanide solution by charcoal has been well known for many years, and finely crushed charcoal has actually been employed as a precipitant in place of zinc in certain Australian cyanide plants.†

In the ordinary limekiln alternate layers of fuel and limestone are fired, so that the burnt lime is usually contaminated with unconsumed carbonaceous matter. Wood is used in some mining districts for burning the lime employed in cyaniding, and although such burnt lime usually contains appreciable quantities of unconsumed charcoal, yet the deleterious effects of such a constituent, which increases in proportion to the amount of lime used, does not appear to have been seriously considered. Many hundred tons of burnt lime are used monthly in cyanide plants in South Africa, and usually contain unconsumed carbonaceous matter from the coal employed in burning. That the bad effects of this ingredient should

be recognized as causing loss of gold, by precipitating it from solution in the sand and slime charges, is shown by the following tests, among others: (a) A sample of partly burnt coal from commercial lime was crushed through a 20-mesh screen; 34 gm. of this powdered coal and 1105 c.c. of 0.02% working cyanide solution was given 6 hours intermittent agitation in a filled and closed flask, followed by 12 hours contact, when 0.09 dwt. of gold per ton was found in the filtered solution, while the carbonaceous precipitate assayed 0.49 dwt. per ton of solution, so that 84.5% of the gold had been precipitated. (b) 17 gm. of coal from burnt lime was crushed through a 30-mesh screen, and added to a litre of 0.021% of working cyanide solution, assaying 0.51 dwt. per ton, in a large dish. The mixture was stirred occasionally for 8 hours, followed by 14 hours quiet contact, when on assaying the filtrate it was found that all but a trace of gold in the solution had been precipitated. (c) A glass tube, $\frac{5}{8}$ in. diam. and 12 in. deep, was filled with finely crushed, half-burnt coal, excluding the 90-mesh grade, from commercial lime, and 2850 c.c. of working cyanide solution assaying 1.34 dwt. per ton was slowly percolated through the column during 26.25 hours. The percolate was assayed at intervals and showed only traces of gold.

Tests with fresh unheated coal showed little or no precipitating effect from a cyanide solution, which appears to indicate that the precipitating agency in coal which has been partly coked by heat does not exist in fresh coal, but is probably due to the hydrogen formed by the decomposition through distillation of coal, and occluded in the residual solid.

Assuming that ordinary burnt lime contains only a small fraction of 1% of carbonaceous matter, this is equivalent, in a large plant, to several pounds of precipitant per day, which comes in contact with dissolved gold in the sand and slime charges. It is, hence, obviously desirable to use lime which does not contain carbonaceous matter. In case it is impossible to obtain lime free from carbonaceous matter, the only remedy appears to be to dissolve the lime required in the mill-service water before entering the battery. Water can dissolve about $2\frac{1}{2}$ lb. of calcium oxide per ton, and since only dissolved lime is efficient, it would thus be possible, though somewhat troublesome, to prevent the carbonaceous matter in the lime from coming into contact with the ore at all, provided that all insoluble matter were settled in the mill-service water-tanks.

Since carrying out the above experiments some work has been done at the Knights Deep to utilize the precipitating effect of half-burnt coal, and a good many tons of waste acid solution have been passed through an extractor box containing crushed granular fragments of coal (between 10 and 100 mesh), sorted from the ash-dump, with the result that a coal product assaying 12 oz. per ton was obtained. It has also been found that some base metals, such as copper, lead, and mercury, are likewise precipitated from their solutions by coal which has been heated. In view of the results obtained, the application of this method of precipitation has been provisionally protected by patent in the usual manner, and attempts are now being made to develop it.

*Read at meeting of Chem. Met. & Min. Soc. of S. A., April 17, 1909.

ARTEAGA DISTRICT, CHIHUAHUA, MEXICO.

Written for the MINING AND SCIENTIFIC PRESS
By W. B. WINSTON.

The district of Arteaga lies in the southwestern part of the State of Chihuahua, on the western slope of the Sierra Madre. The nearest town of importance is Chinipas, situated on the Chinipas river, about eight miles distant toward the east. At present the nearest railroad connection is the city of Alamos, Sonora, the terminal of a branch of the Cananea, Rio Yaqui & Pacific. The distance is about one hundred

Chinipas, Chihuahua.

miles, half of which is traversed by a good wagon-road to San Bernardo, and the rest by a good mule-trail. Additional and better shipping facilities will, however, be provided in the near future. The Kansas City, Mexico & Orient railroad is now engaged in the construction of a line from Topolobampo, on the Gulf of California, to Miñaca and Chihuahua, and trains have for some time been running from the City

Guadalupe Mine.

of Chihuahua to Aguatos. There remains but a small portion to complete, when the road will be in full operation. The Arteaga district is only about 50 miles from this new railroad.

For shipments by water the port of entry at present is Agiabampo, on the Gulf of California. Freight charges from San Francisco to the mine amount to about \$45 per ton of 2000 lb., including transportation to San Bernardo and thence into the mountains by mule-back.

The district of Arteaga is highly mineralized and has been an abundant producer of gold and silver since the early days, when many properties were worked.

A series of parallel fissures traverse the district from north to south, and where not covered by overlying rhyolite can be traced on the surface at many places for a distance of over 3000 metres, with a fairly constant width and strike. The average width on the surface is from 5 to 8 ft., whereas in the underground workings it ranges from 4 to 30 ft., or even more. This increase in the width is generally to be attributed to the intersection of spurs or feeders, and these

On the Road From Alamos to San Bernardo.

produce strong local enrichments. The junctions generally occur on the hanging-wall side. These fissures occur in a fine-grained diabase dike which intrudes through the granite.

The veins dip 25 to 30° east, as far as the deepest workings show, and the diabase on both the foot and hanging walls is remarkably smooth and firm. So much so that stopes over 200 ft. high by 200 to 300 ft. long and 4 to 30 ft. wide, have been standing with-

Chinipas River, Showing White Chief Mine Buildings.

out timbers for over 50 years and are today perfectly safe.

The vein-filling is a bluish white quartz, yielding in places to a brecciated material. The best ore found in the district is quartz containing argentite, with sulphide of iron and free gold. The ratio of silver to gold is about forty to one. The ore yields readily to treatment, giving about 50% recovery of the gold on the plates.

Water for milling and other purposes is available in sufficient quantity from the Chinipas river, and wood for fuel and mine-timbers is obtainable at reasonable cost. The wood used for fuel can be laid down at the mine for P7 per cord of 128 cu. ft., and

hardwood or pine timbers 8 to 12 ft. long by 8 to 12 in. diam. cost about 12½ cv. per linear foot delivered, while ordinary pine wood is delivered for ₧60 per 1000 ft. board measure.

Mexican labor can be had at all seasons of the year, the usual wages being ₧2 per day for mill hands, stationary engineers, and the like; ₧1.50 to ₧2 for miners, and ₧1 per day for peones and laborers. The climate is agreeable, being neither hot nor cold, and it has its wet and dry season—in fact, two each year. The first wet season extends from the end of June to September, and sometimes into October; a dry season then intervenes until December or January; during January and February occur winter rains; after which comes the long dry season, lasting until June.

The principal mine in the Arteaga district is that of the White Chief Mining & Milling Co. Its properties consist of the following: Guadalupe, East, West, and North Extensions of the Guadalupe, the Carmen, One and Two, the San Miguel del Castillo and Extensions, Mina Grande, and Veta Madre, embracing altogether 57 pertenencias, or about 120 acres of mineral ground, together with 700 acres of additional land. The claims composing the group extend for a distance of 6000 ft. along the strike of a series of parallel veins varying in width from 3 to 8 ft., and giving values of from \$3 to \$8 gold on the surface. These croppings are readily traceable except where the lava capping covers the crest of the hills. The Chinipas river crosses the southern boundary of the company's property close to the point where the mill is situated. These mines have probably been worked intermittently for more than 200 years, and judging from the extensive workings and the absence of waste-dumps, both on the surface and underground, the yield must have been considerable, both in quantity and quality.

At present there are about 10,000 ft. of underground workings aside from the open stopes, and most of these are in ore assaying from \$8 to \$30 per ton. An arroyo running east and west about midway through the property makes it convenient to divide the holdings into north and south groups. All workings in the north group are connected with a shaft about 350 ft. deep, while the south group is worked through adits; work is now under way to connect the south group with the main shaft. The shaft is equipped with a 50-hp. plain slide-valve engine, two boilers, and two air-compressors. Machine-drills are used throughout the mine. Machinery for a new mill has been shipped from San Francisco. The method of treatment consists of crushing the oversize from the grizzly in a Dodge crusher, stamping, amalgamation on copper plates, sizing and concentration on Wilfley tables. The sand is treated by cyaniding and the slime is impounded. The average working-cost has been about ₧7.50 per ton for mining and milling, including development work. The concentrate, precipitate, bullion, etc., are sold on the ground to an agent of the National Metal Company.

I was told that the gross value of the probable ore

is about \$500,000. At present the White Chief M. & M. Co. is employing 150 men.

The most important mines adjacent to the district of Arteaga are the Palmarejo and Mexican Goldfields Limited. These properties have been steadily producing for more than 100 years, and as late as 1906 had an output of ₧75,000 monthly. The Geraxelterana, Santa Barbara, Monterde, Durasnos, San Augustine, and several other properties are the producers of the adjacent Palmarejo district. There are also many smaller properties in a state of development. Besides gold and silver, both the Arteaga and Palmarejo districts are producers of copper and lead to some extent.

The Clinton formation lies on the flanks of a non-symmetrical anticlinal valley, extending northeastward for about 50 miles, with the city of Birmingham near the middle. Only on the east limb of the anticline in Red mountain, near Birmingham, is the ore of commercial value. Northwest of this valley lies the Warrior field, containing coking coals, while to the southeast lies the Cahaba field, containing high-grade steam and domestic coal. Cambro-Ordovician dolomite within the valley and Mississippian limestone between the ore-outcrop and the coalfields both afford stone for fluxing. The topography is of the ridge and valley type, favorable for transportation lines. The ore is of sedimentary origin. It contains approximately 36% iron, 12 to 25 silica, 8 to 20 lime, and 0.33 phosphorus. It occurs in beds like coal, but they are subject to residual enrichment on the outcrop; also they are not so broadly extensive as coal beds. Studies of the strike-sections of the ore on the outcrop and of sections at right angles to the outcrop by means of mine-openings and drill-records show that the beds are long, narrow, lens-like bodies. The quality of the unweathered ore is fairly constant in the direction of the dip. All the facts obtained during recent geological surveys of this field, according to Ernest F. Burchard, indicate that the ore is the result of original deposition of ferruginous sediments.

Mining in the southern Appalachian region dates back to the beginning of history in America. The principal mineral resource is gold. When the early Spanish explorers came to America they were shown by the Indians rich nuggets and ornaments of gold from the southern Appalachians. The Spaniards mined gold in Georgia in the seventeenth century. From 1825 to the present time production has been continuous. Unfortunately, no reliable statistics of the production are to be had, but to judge from available data it seems probable that the total value of the gold mined has been about \$10,000,000. A considerable but unknown proportion of this amount has been derived from placer deposits, but much the larger part has been won by hard-rock mining. Iron has been mined in the southern Appalachians, and within recent years the monazite industry has attained importance in the Carolinas. Copper, lead, manganese, pyrite, mica, barite, corundum, clay, limestone, and granite have also been found and worked. Besides these minerals, tin ores occur in this region.

THEORY OF THE SETTLEMENT OF SLIME.

Written for the MINING AND SCIENTIFIC PRESS
By HARRISON EVERETT ASHLEY.

A paper on the settlement of slime, by H. S. Nichols, appeared in the MINING AND SCIENTIFIC PRESS, July 11, 1908. From the study of clay-working slips I can add information from a different view-point. In most respects what I submit is supplementary.

In that article no reference was made to the viscosity of the liquid medium. Viscosity is defined as the measure of the internal friction of a fluid. The viscosity of water is commonly taken at a given temperature as unity. In Fig. A is reproduced graphically the variation of the viscosity of water with the temperature. The viscosity decreases as the temperature rises. As the data given in Landolt and Börnstein's tables extend only to 70° C., it was neces-

Fig. A.

sary to extrapolate to get the value for 88° C., the highest temperature used by Mr. Nichols. In his Fig. 2, the settling curves for various temperatures are practically straight lines, so that the intersections of the ordinate for any number of millimetres settled should be in about the same proportions. Taking the 140 mm. ordinate, the following table has been prepared:

Temperature, degrees Fahrenheit.	60	100	140	190
Temperature, degrees Centigrade.	16	38	60	88
Viscosity of water from Fig. A...	62	38.4	26.9	18.4
Viscosity of water, multiplied by 3	186	115.2	80.7	55.2
Minutes settling 140 mm., curves				
for heated liquids	194'	110'	82'	50'
Minutes settling 140 mm., curves				
for heated and cooled liquids...	185'	140'	80'	

Superior figures indicate numbers of curves.

From this table it appears that, within the limits of experimental error, the rate of settling is directly proportional to the viscosity of the water, whatever the temperature corresponding. According to Fig. 1, 5, and 6 of Mr. Nichols' paper, the higher the percentage of solids in the pulp the slower the rate of

settling. In Fig. B, which gives the results of experiments by A. V. Bleining (Trans. American Ceramic Society, 10, 394, 1908), it is shown that the viscosity of a clay-slip increases more and more rapidly as the clay-content increases; consequently the diminution in speed of settling shown in Fig. 1, 5, and 6 of Mr. Nichols' paper can be attributed to increase of viscosity with concentration. As clays differ in viscosity at equal concentrations of slips, different slimes should also be expected to vary. Consequently, a

Fig. 1

treatment adapted to one slime will require its proportions to be altered somewhat to apply to another slime.

To explain the other figures, it is necessary first to discuss the various conditions of matter that may be present in a slime. The coarser particles are crystalloid, and are relatively dense and hard as compared with the finer matter. Upon and surrounding the crystal grains is an enveloping film of matter in the 'gel' form of the colloid condition. It resembles gelatine in properties, absorbs water, and shrinks on drying, becoming hard and cementing the grains together. It is less dense than the crystal grains, and will settle slower than them if separate.

If a large excess of pure water be used, or a proper proportion of a suitable solvent, like ammonia, soda

Fig. 2

ash, or caustic soda, the gel is dissolved and forms a turbid suspension which will not settle clear. This is called the 'sol' form. In most cases it is the soluble sodium, ammonium, or potassium compound of a very large and complex polymerized molecule, in which the sodium or other part is an exceedingly small part of the whole. This is illustrated by cases 1a, 1b, 2a, and 2b of Fig. 4 (from Mr. Nichols' paper). If to such a sol, sulphuric acid be added, the acid takes away from it the base that made it soluble, and the gel form of the colloid is precipitated and will settle. If barium chloride or lime is added the reaction is something as follows:

The insoluble barium or calcium compound is formed, and will settle readily. If salt (NaCl) is added, it merely 'salts out' the sol; that is, when salt comes into the solution the sol has to go out of

the solution until a solubility-equilibrium is reached. In Mr. Nichols' experiments, as he has indicated, nearly equal results were obtained by the following:

	H ₂ SO ₄ .	BaCl ₂ .	CaO.	NaCl.
Mg. per 200 c.c. pulp containing 2.5% solids....	16.68	83.32	55.54	166.90
Chemically equivalent proportions used	0.34	0.77	1.98	2.89

On figuring to a basis of chemically equivalent proportions, it is seen that salt is much less effective than the other chemicals as a cause of coagulation. The lime does not show up very well on the equivalent basis, for a reason to be explained further on.

The fourth condition of matter is that of true solution, into which form the various soluble salts must be brought in order to act as precipitants. Now mat-

ter sedimentation by forming insoluble compounds. A second way in which they may accomplish the same object is by decreasing the amount of OH ions present in the liquids. Both OH ions and all forms of clay particles in water are negatively charged. The OH ions appear, with most clays, to have a marked effect in causing the clay colloid to assume the sol form; while a depression of the number of OH ions tends to coagulate the sol and form the gel. The reason for the comparatively weaker action of lime (CaO) as a settling agent is that, while it forms an insoluble compound, it also increases the OH concen-

ter in all four of these conditions is acted upon both by gravity and by electrostatic repulsion. The repulsion is between particles having charges of the same sign. In the case of true solutions, the size of the dissolved molecules is so small that the electrostatic repulsion far outweighs the effect of gravitation, and the particles are uniformly diffused throughout the liquid. The sol is the first step in aggregation; the particles are large enough to reflect light, and while electrostatic repulsion still predominates, the effect of gravity is to make the upper layers of the liquid somewhat less concentrated than the lower. The gel and the crystal are the irregular (or amorphous) and the regular forms, respectively, of the solid state. The opposing effects of gravity and viscosity largely predominate, but electrostatic repulsion is partly responsible for the slow settlement of the finest grains.

It was shown above that electrolytes may promote

tration of the liquid, two opposite influences on sedimentation. Sulphuric acid, on the other hand, not only destroys the soluble compound, but it also decreases the OH concentration. With 4% H₂SO₄ the viscosity is about 6% greater than that of water, but these other effects predominate. Sulphuric acid is therefore a most effective coagulating agent.

Mr. Nichols' fourth deduction, that close packing of the clay particles will render the electrolyte inefficient and finally of no avail, is not exactly in accord with clay-working experience. Carbonate of soda (Na₂CO₃) is commonly added to clay slips, with the result that they require about half as much water to be capable of pouring as would be the case without the addition. Addition of acid sufficient to neutralize the soda stiffens such a slip again. This example is, however, with more dense slips than in the cases considered by Mr. Nichols.

COMPANY REPORTS.

COPPER RANGE.

The annual report of the Copper Range Consolidated for the year 1908 shows that the Baltic Co. produced copper at a cost of less than 7¼c. per lb., a notable achievement for a Lake Superior mine recovering but 23.19 lb. of copper per ton of ore treated. The exact cost, excluding construction as an operating charge, was 7.72c., as compared with 8.75c. in 1907. Similar costs for the Champion were 8.34 and 9.05c. The copper recovery from the rock at the Baltic in 1907 was 21.94 lb. per ton; in 1908 it was 23.19. At the Champion the recovery in 1907 was 23.26, and in 1908, 22.38. Baltic's cost of \$1.50 per ton of rock treated, or \$1.56, including taxes, is a figure which few mines, if any, in the Lake Superior district can duplicate.

The net quick assets of the Copper Range group of properties on December 31 were \$1,300,000. The Copper Range Consolidated was obliged to draw upon its surplus to the extent of \$272,779 for the payment of construction and a dividend of \$4 per share, the result chiefly of the low price of copper, the average for the year being 13.39c. Trimountain, while contributing practically nothing last year toward the \$400,000 paid in dividends on the Copper Range shares given in exchange therefor, was able to show a surplus over construction of \$41,842.

Up to the present time, or since Baltic first started as a producer in 1898, it has sent out over 107,000,000 lb. of copper. Since 1902, when the Champion mill started up, this property has produced 93,800,000 lb., while Trimountain has a record of over 59,000,000. Up to the close of 1908 Baltic has paid \$45.50 per share, or \$4,550,000, in dividends since 1905, while Champion since 1903 has paid \$42 per share, or \$4,200,000. Including \$800,000 paid by Trimountain, these three South Range mines, pioneers in the territory which they have opened up, have paid their owners total dividends of \$10,550,000.

UNITED STATES SMELTING, REFINING & MINING CO.

Despite low prices for metals, the above splendid company, with the superfluous amplitude of name, paid 4% on common stock, after meeting all fixed charges for the year 1908. The metals sold and prices realized were:

Metal.		Value, %	Price, c.
Copper, lb.	32,803,603	34.5	13.27
Lead, lb.	27,304,347	10.0	4.23
Silver, oz.	8,340,566	34.5	52.97
Gold, oz.	128,206	21.0

These include metals from custom ores and the Mexican production. During the year the capital expenditure was increased by \$996,300, distributed as follows:

Mining properties	\$203,626
Smelter buildings and plant at Bingham	
Junction, Mammoth, and Chrome	362,619
Mills, mine buildings and other equipment..	208,126
Refineries at Chrome and Graselli.....	71,504
Stocks in subsidiary companies and in Bul	
lion Beck and Champion	150,425

\$996,300

From the properties in Bingham were extracted 21,487 tons, and from the Centennial Eureka 112,855 tons of ore. The output of the Mammoth mine in California was 322,003 tons, and the smelter at that point treated 436,275 tons of charge. From the Richmond-Eureka were taken 25,374 tons of low-grade ore for flux. The report gives assurance of excellent conditions as to ore reserves in all the mines mentioned, but no figures are presented. The interesting statement is made that the Buchanan mine in California, purchased during the year, bids fair to develop into a source of considerable profit, and that "there is now in sight ore enough to cover the purchase price." When mines are bought and sold on such a basis as that, the element of risk will be eliminated as far as can be from the concerns of men. It is also stated that a number of mines were investigated during the year, none of which it was deemed wise to

purchase. The company definitely announces that it has "adopted an aggressive policy of investigation and extension, and a liberal appropriation has been set aside for such work." Expansion is the watchword among all the great copper producers; the leaders show no sign of skepticism regarding the future. The net earnings of the United States company for 1908 were \$3,398,488, out of which dividends absorbed \$2,410,783. The report is a simple business-like statement which gives the answer to the essential details that interest the great bulk of stockholders.

TONOPAH.

The seventh annual report of the Tonopah Mining Co. of Nevada shows total investments amounting to \$2,509,912, an increase of \$73,224 net. During the year \$65,560 was charged off as depreciation, and there was a decrease of \$12,746 in the amount of stocks and bonds owned. The increase was due to loans and advances to subsidiary companies. The current assets, including "net value of ore on dump, \$248,349," amounted to \$754,700. The combined incomes of the Tonopah Mining Co. of Nevada and the Desert Power & Mill Co., were \$1,751,098, of which \$750,000 was paid out in dividends and \$1,001,098 carried over as surplus. W. H. Blackburn, superintendent of the mine, reports that 234,017 wet tons were hoisted from the Mizpah, Silver Top, and Red Plume shafts. Of this, 155,401 dry tons of ore, having an average value of \$23.43 per ton, were shipped to the mill at Millers, 7957 tons were placed in storage, 13,635 of low-grade ore were placed on the dump, and 50,296 tons were waste rock. The mining costs were \$4.60 per ton of dry ore shipped, \$3.31 per dry ton hoisted, or \$4.80 per dry ton of ore shipped if cost of sinking, station cutting, and diamond-drill work be included. The ore reserves March 1, 1909, are computed at 367,304 tons worth \$21.11 per ton, with gold at \$19 per oz. and silver at 50 cents.

A. R. Parsons, superintendent of the mill, reports an average of 93.8 stamps dropping, out of a total of 100. The dry ore crushed amounted to 158,052 tons, averaging 0.354 oz. gold and 31.13 oz. silver. From this 1504 dry tons of concentrate averaging 4.74 oz. gold, a total of 7125, and 689.46 oz. per ton, or a total of 1,036,953, of silver, were produced. By cyanidation 42,914 fine ounces of gold and 3,423,772 of silver were recovered, making an average metal recovery of 90.3%. The average price of silver for the year was 52.16c. The average direct cost per dry ton of ore milled amounted to \$3.45, to which 72c. should be added for general expense. A large amount of development was accomplished.

PRESTEA BLOCK A, LTD.

This corporation owns portions of the Essarman and Intermediate concessions, in the Prestea district, near Anco-bra river, Gold Coast, West Africa. The authorized capital is £500,000. The ore reserves on March 31, 1909, were estimated at 270,500 tons, having an average assay value of 11.6 dwt., and 25,000 tons, partly developed, at 12 dwt. In 1908, 89,933 tons were milled, with a gross value of £152,541. During the year several important additions were made to the plant, but owing to the flooding of the shaft, development was limited. The costs per ton in 1908 were as follows: mining, 17s. 4.64d.; milling, 10s. 5.57d.; general at mine, 3s. 1.34d.; development, 1s. 1.11d.; London expense, 1s. 2.16d.; depreciation, 2s. 7.51d.; a total of 35s. 10.33d. The value of the gold, including concentrate, recovered amounted to 34s. 5.01d. per ton. It is expected that the Government railway from Tarkwa to Prestea will reach the mine in 1909. This will reduce costs materially.

BRITISH BROKEN HILL.

The British Broken Hill Proprietary Co., Ltd., owns mines in New South Wales. The directors' report for the half-year ending December 31, 1908, tells very little about them or the year's business. The statement is made that "after allowing the usual depreciation, the half-year's expenditure amounted to £7351 17s. 0d., which has been charged to the profit and loss account, the balance of which is thereby reduced to £19,360 18s. 10d." Development amounted to 333 ft. No estimates of ore reserves are given.

Lead Production in 1908.

According to smelter returns as compiled by C. E. Sieben-thal, for the U. S. Geological Survey, the lead production in 1908 was 408,523 tons, of which amount 310,762 was produced from domestic ores. The returns from refiners give slightly different figures, as shown by the following tables:

PRIMARY LEAD.		
	1907.	1908.
Desilverized lead	284,432	265,564
Soft lead	99,948	101,013
Desilverized soft lead	29,809	29,856
<hr/>		
Total primary lead.....	414,189	396,433
Production of antimonial lead...	9,910	13,629
<hr/>		
SECONDARY LEAD.		
Pig lead	9,990	7,840
Lead in alloys	15,508	10,443
<hr/>		
Total recovered secondary lead	25,498	18,283

The figures of domestic production are based upon returns by the smelters; all other figures are from the records of the Bureau of Statistics. Decrease by liquidation covers losses in smelting and refining in bond, and other corrections. Warehouse stocks of bonded lead of foreign origin are given, but it has been found impossible to obtain at this time complete figures of domestic stocks. For this reason the result given below is 'lead available for consumption.' The 'apparent consumption' of previous reports would be this quantity, increased or diminished by the increase or decrease of domestic stocks during the year, and also diminished by the exports of domestic lead. The domestic lead exports consist of lead in manufactures and in type, as shown below. In the following table 'lead' includes all kinds—lead in ore, base bullion, pigs, bars, and old:

Supply:	1907.	1908.
Stock in bonded warehouses Jan-uary 1	5,756	12,944
Imports—		
For consumption	15,246	9,805
For warehouse	64,569	102,241
Domestic smelter production.....	365,166	310,762
<hr/>		
Total supply	450,737	435,752
Withdrawn:		
Exports of foreign lead	51,447	76,357
Exports of foreign lead in manu-factures under drawback	8,628	9,254
Decrease by liquidation	4,578	13,425
Stock in bonded warehouses De-cember 31	12,944	18,565
<hr/>		
Total withdrawn	77,597	117,601
<hr/>		
Available for consumption	373,140	318,151
DOMESTIC EXPORTS.		
Type	364	241
Lead manufactures	\$686,097	\$558,640

Modern Milling Plants.

Utah is rapidly making a world-wide reputation for itself by the magnificent scale upon which its more recent reduction works are being constructed. In fact, the State promises to distance all others in the magnitude of its reduction works, and especially in the line of milling and concentra-tion. With the large plant of the Utah Copper Co. now run-ning at full capacity, that of the Boston Consolidated, which is also nearing its intended output of 3000 tons per day, there will soon be classed the plant of the Ohio Copper Co., which is now receiving finishing touches and is situated close to the mines at Bingham. The mammoth concentrator of the Ohio Copper Co., being the latest in the field, and hav-ing had the benefit of the results and mistakes of others, promises to excel all former enterprises of this nature, espe-cially for the reduction of the low-grade sulphides, for which Bingham is now so universally known. This plant is being

built upon a liberal scale, in a most thorough and substan-tial manner, with concrete foundations for its buildings, as well as for all the heavy machinery, while for the building itself, a most substantial and improved type of steel con-struction has been adopted. It is being laid out in four units, each having a nominal capacity of 500 tons per day, and so arranged as to permit of each one being operated independently. While the general plan of arrangement and treatment is simpler and more direct than that adopted by the other works treating the same character of ore, the plant itself will be notable for the massiveness and substan-tial character of its reducing machinery.

Equipping this plant involved placing the largest order for crushing machinery that has ever been given in the United States, or elsewhere. The crushers will have ample capacity for fully 3000 tons per day, and they are of the latest improved Blake style. The fine-grinding is to be done by means of 7-ft. Monadnock mills, of which four machines are provided for each of the four sections of the plant, and as the capacity of each of these mills is placed conservatively at 150 tons per day, with a probability that it will reach 200, it can easily be seen that a 3000-ton capacity can appropri-ately be claimed for this plant. The above machinery is be-ing supplied by the Trent Engineering & Machinery Co. of Salt Lake. It amounted to 1,600,000 lb. weight.

Commercial Paragraphs.

The MINNEAPOLIS STEEL & MACHINERY Co. has recently opened a branch office at 324 Dooly Block, Salt Lake City, Utah, which will be called the Mechanical Department, and will be in charge of O. P. Cherdron.

THE C. O. BARTLETT & SNOW Co., Cleveland, Ohio, an-ounces that a branch office has been established at 50 Church street, New York, which will be in charge of H. H. Bighouse, chief engineer for the company.

CHALMERS & WILLIAMS, Chicago, have recently sold a five-stamp mill to M. K. Rogers, for use in Alaska; a Kennedy gyratory crusher, two sets of rolls, and 12 Frue vanners to the Bunker Hill & Sullivan M. & C. Co.; and a 3½-ft. Hunt-ington mill plant for Cape Gracias, Nicaragua.

THE CYCLONE DRILL Co., of Orrville, Ohio, has recently made shipments to the following: E. C. Hargrave, Port Arthur, Canada; the Rio Tinto Co. for railroad construction in Spain; W. H. C. Downes, Western Australia; the Santa Rita Co., in New Mexico; Rockdale Iron Co., in Tennessee; Napier Iron Co., Tennessee; G. A. Amsinck & Co., Colombia.

Catalogues Received.

FRANK HUNTZIKER has joined VICTOR RAKOWSKY at Duluth, Minnesota, as associate mining engineer.

The WESTINGHOUSE ELECTRIC MANUFACTURING Co., Pitts-burg, has just published circular No. 1502 on distributing transformers.

THE J. GEO. LEYNER ENGINEERING WORKS Co., Littleton, Colo., is distributing its Bulletins No. 1002 and 1004, which are just off the press.

The A. LESCHEN & SONS ROPE Co., St. Louis, has just pub-lished a book of views of the Lake Tramway at Chicago, which they will send to anyone interested.

The ROBINS NEW CONVEYOR Co., New York, has recently published an attractive little booklet describing its Genuine Balata belting for power transmission and conveying.

THE GOULDS MANUFACTURING Co., Seneca Falls, New York, is distributing its new power-pump catalogue, which is a 190-page, handsomely printed and illustrated book. In it are included a discussion of the principles involved in triplex pumps, many pages of useful information and tables, a com-plete index, and telegraphic code. No library of trade cata-logues is complete without this volume.

Dividends.

On Friday, June 4, 1909, the Bunker Hill & Sullivan Min-ing & Concentrating Co. paid dividend No. 41 of \$45,000. This makes the amount of dividends paid since January 1, \$345,000, and the total to date, \$11,016,000.

EDITORIAL.

LIKE A RICHARD born with teeth, the International Smelting & Refining Co., only a few months old, promises dividends of 10 per cent on \$10,000,000 of issued stock.

BOSTON signaled the acquisition of control of the Osceola mine by the Calumet & Hecla by bidding up the stock. The confidence displayed is vindicated in the results. The Osceola is producing 4800 tons of ore per diem, from which the net recovery is 17½ pounds of copper. This indicates an earning power equal to \$10 per share.

FOR PRESIDENT of the American Mining Congress the name of Mr. James Douglas is being mentioned. His selection would be a particularly happy one, and would do much to strengthen the organization. It is understood that Mr. J. H. Richards, who as president has, with rare devotion and sacrifice, guided the Congress through several stormy years, desires to retire. Mr. Douglas would make an ideal successor. His broad knowledge, high character, and keen interest in public affairs makes him a powerful leader. Under his guidance the Congress might well come to be a most influential organization, guiding opinion and legislation to the advantage of every department of the mining industry.

TOPOGRAPHIC SURVEYS are of large importance to mining and engineering development. In this country they have been executed mainly by the United States Geological Survey. Beginning as a mere incident to geological mapping, they have expanded with the demand until now a complete topographic map of the country is being made. This work is too large to be done within a single generation by any one agency, and gradually the States have been brought into co-operative relations with the Federal Survey. In general the expense of the work has been divided equally, but the Federal Survey has recently been unable to accept all the help offered on the old terms, and misunderstandings and friction have resulted. Mr. George Otis Smith, the Director, has taken the matter in hand and has prepared a systematic plan for meeting co-operation. We are glad to present the details on another page. The matter is worthy of careful consideration and discussion by engineers and geologists, since it affects all parts of the country.

TRADE-SHIPS instead of battle-ships to preserve the peace of the Pacific, is the proposal of Mr. Thomas J. O'Brien, our Ambassador to Japan. Some matters, in the interest of sincerity, ought not to be discussed in public by a diplomat, and the question of national armaments is one of them. The fighting

equipment of a nation is argument enough; the foreigner knows from its strength whether it be able to protect commerce or not. If it cannot, war and reprisals are invited; if it can, then peace can be maintained. The best insurance policy upon the unobstructed expansion of commerce is a powerful navy. We do not say this in the interest of the steel manufacturers, nor of the nickel and copper producers. We merely invite Mr. O'Brien to point to any important merchant marine in the world, present or past, that has been developed without an adequate naval guarantee of protection. A brief consideration of the teachings of French and English history would save our representatives abroad from stultifying us by such post-prandial gush. To seek favor in the eyes of our rivals by such utterances is only to excite contempt.

CHINA is said to be resentful over the way the position of American minister to that country is being hawked about. This is not surprising. The administration's attitude in the matter is inexplicable. The post at Peking is in many ways one of the most important in our diplomatic service. The problems arising there are peculiarly complex and delicate. At present, principally because of our stand for the 'open door,' America is in favor at the Chinese court, and since the reformation of the consular service we have been well represented in the Empire. We are looking to the Orient for a larger commerce and for closer ties in the future. Within a few days announcement has been made that American, as well as German, French, and British, banks are to participate in financing the Hankow-Sze-Chuen railroad, and for the first time this has been brought about by the direct influence of our diplomatic representatives. This, in view of Mr. Taft's known interest in Far Eastern affairs, marks it as peculiarly strange that the position of Minister should be offered to a discredited politician such as Mr. C. W. Fulton, former Senator from Oregon, even with the explanation that it was arranged that he should decline. Since, according to report, Mr. J. A. Hemenway, ex-Senator from Indiana, Mr. John Hays Hammond, and Mr. Frederic Delano, the accomplished president of the Wabash railroad, have all had the opportunity to decline. Mr. Nelson W. Cromwell, it is stated, would have been similarly complimented, except for the danger that he would accept and that the Senate would refuse to confirm his nomination. Numerous others have been mentioned. Among the latter, Mr. J. W. Jenks, of Cornell University, is the only one who is really qualified for the position by training and actual experience in the Orient. His appointment to the Court where scholars and scholarship are especially esteemed would have much to commend it. The others are excellent gentlemen, but the appointment of any of them would be obviously in the nature of dividing political spoil. The use of so important an embassy as a means of settling accounts accumulated during a political campaign is shameless. It insults our neighbor, forfeits respect, and injures commercial relations. The position should be promptly filled by transfer of some one of the many able men in the service.

Phosphate on Public Lands.

A battle is to be fought at the next session of Congress over the conservation of phosphate resources in the United States. The question touches far more than the lands containing phosphate deposits. The amount of phosphorus exported in food products is as serious a form of loss as that involved in the exportation of fertilizers. The prevention of exportation, except as a war measure, is not permissible by our Government, and the commercial weapon of an export duty is expressly withheld by the Constitution. Restriction of the output of phosphate, therefore, would seem to be questionable as a measure of national economics. If the agricultural lands are less productive for want of fertilization the farmer will have less to sell, and prosperity will be checked. The advocates of restriction have not made it clear how that policy will improve conditions. It will dole out the treasure of phosphate stored in the hills of Wyoming, Idaho, Utah, New Mexico, and Arizona for a longer period, and the benefit, if any, would apparently accrue mainly from the wisdom that is supposed to be born of adversity. The farmer in need would learn to be a conservator in ways now lightly considered. The loss of soluble ingredients from the soil by drainage is an enormous factor in the impoverishment of the country. While not altogether preventible, methods of tillage can restrict such losses to a considerable extent, and the use of soluble fertilizers in excess, which is a cause of serious waste, can be avoided by the application of finely ground insoluble phosphates and potash minerals, which will be slowly converted to soluble forms by the acids in the soil. Thus fertility may be sustained.

The Committee on Public Lands at its hearings this spring was bombarded by suggestions. Mr. Frank Pierce, of the Department of the Interior, proposed a leasing system, permitting restrictions upon exportation and monopoly. His statement that the Department was willing to issue patents to locators of claims on phosphate lands, whether lode or placer, might be construed as representing the opinion of the Secretary of the Interior; but he suggested that the matter be referred to the courts for ultimate determination of the category to which such claims should be referred. The fact seems to be that the Department is quite ready to issue patent for phosphate claims under the placer provisions of the law, but will probably decline to take responsibility where they were located as lode-claims. A tendency was displayed on the part of some to limit the rights of those who had already located under the lode law, to the vertical bounding planes, which indicates that some have not yet learned that retroactive laws which affect vested rights are unconstitutional. Locators of claims, the character of which may be in doubt, should always take the precaution of covering the same ground with both placer and lode-locations. Application for patent can be made for either, and title to one or the other is sure to issue. Those who have in good faith located phosphate lands as lodes are in danger of losing their rights. If the courts should decide that they are placers, within the meaning of the law, there would be no remedy. It is

feasible to amend the locations, setting forth that error had been made in determining the character of the ground, and claiming title under the placer law. The courts in such case would almost certainly follow the precedent which recognizes the right of the discoverer. Mr. A. B. Browne, representing the San Francisco Chemical Company, was inclined to believe that the courts, by virtue of this spirit to uphold the first in time as the first in right, would confirm the claims of locators according to either principle. This is open to doubt.

The authority of the Department of the Interior to withdraw the phosphate lands from location is another debatable question. The courts have not passed upon it, and until they do, no one can affirm that locations made at the present time in defiance of the Executive order would not be declared valid. The law expressly sets forth the right of location upon public lands, and only an act of Congress can withdraw that right. In the case of National Parks, legislation has definitely closed those areas to location for minerals. Until a statute shall have placed the phosphate lands upon a different basis they belong to the people in compliance with the provisions of the mining law. At all events location cannot be prevented. The most that can result from the Executive order of withdrawal will be to deny applications for patent, and the right of the locator to obtain such patent can then be determined in the courts.

Tariff on Oil.

Congress has become involved in peculiar difficulties in attempting to frame an oil schedule for the tariff bill. It is found to be hard to make a revenue bill serve campaign purposes in 'trust busting' and yet keep it from hurting either trusts or independents. In the House, with great enthusiasm crude oil was put on the free list, for the avowed purpose of hurting the Standard Oil. Greatly to the astonishment of many people, the dread monopoly has continued calm and unruffled, while the 'Independents' have protested vigorously and at length, that the oil producers, rather than the Standard, would be hurt.

The Standard Oil Company is mainly in the business of transporting, refining, and marketing oil. It produces relatively little 'crude'. After reading the recent literature on the subject, it will surprise many to be told that the oil business is one of those in which the small capitalist has now the freest opportunity. It costs but little to take up leases and to put down a few wells, and if oil in quantity be found, the Standard can be depended upon to take the product at the well and to pay cash. The market is assured, and not even ore is so salable. Many men have become rich by finding oilfields and selling their output to the Standard. The policy of the Company has seemed to be to encourage the finding of new fields, and to restrain production in the old ones. When the many peculiarities of oil occurrence, and the great waste involved in the sudden production of immense quantities of petroleum in new territory, is taken into account, a rational basis for this policy is apparent. The limits of the field being once known, it is better to hold the oil in the ground than to bring

it to the surface, with consequent loss by leakage, evaporation, and interest charges. Markets grow with population and industry, but oil-production increases by no known or regular law. There are many evidences that supply and demand do not fix the price of American oil, and this is perhaps as often a blessing as a hardship.

There is always the menace, and often the realization, of a sudden and large production of 'crude' from a new field. A few years ago it was Texas and the Gulf Coast, then California, Oklahoma, Illinois, and now it is Mexico. The Gulf Coast is still potential dynamite, and from many other quarters sudden and disturbing production may come. This is a natural risk of the business. Mexican oil is feared only as it may develop—not as it has so far become a factor in the market. A tariff is asked to permit an easier adjustment of industry in the event that the Mexican fields should furnish a large quantity of cheap 'crude' at tidewater. The Standard could use this to advantage. The independent refiners could not. This would enable it the better to undersell the smaller refiners, and at the same time would reduce the amount of oil taken from domestic producers. It is probable, though by no means certain, that prices of crude oil would be locally reduced. At any rate, the reduction in the percentage of production taken would reduce the immediate value of leases. That would make easier the gathering in of proved production, which is now apparently a part of the Standard's policy. Our own resources would be conserved, and cheap foreign raw materials would be manufactured here to be sold abroad at a material advance in price. Economically this is all to our advantage, with the single exception that the hold of the monopoly on the oil industry would seemingly be strengthened. It is well to remember, however, that Mexican oil is of low grade, and is mainly valuable for fuel. Great quantities can be absorbed in Mexico, as are similar quantities of California oil on the Pacific Coast, in doing work elsewhere done by coal. Neither Mexican nor Californian 'crude' is high in the lighter oils. Indeed high-grade East Indian oil is now imported into California for refining. If large quantities of oil suitable for refining be found in Mexico, the discovery will materially affect the world's markets. Every time we refuse to take Mexico's freely offered raw materials, we stimulate her own manufacturing industries. Shall we refine Mexican oil here, or shall it be refined in Mexico at perhaps lower cost and meet our own oil in competition abroad? It is only a choice of where we will meet competition.

These difficulties in the attempt to frame a tariff law in the way it is now being done, illustrate the fact, we believe, that the problem of control of monopolies must in any event be fought out squarely as a separate issue. It is overworking the tariff idea to make it hit the trusts, protect home industry, and provide revenue, all at one time. The 'shot-gun prescription' of the old blood-letting school of physicians has been superseded by more intelligent therapeutics. It were time that we apply higher wisdom to the tariff, and make it serve its purpose in a direct way, or create a commission to adjust it in accordance with the needs of trade and revenue.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

WM. BAYLEY, Jr., is at Paris.

W. S. NOYES is at Shafter, Texas.

C. C. BRACKEN is at Mocerito, Mexico.

L. W. POWELL has been in Los Angeles.

R. G. HANFORD has returned from the East.

C. W. PURINGTON was in Yokohama May 30.

SEELEY W. MUDD has been at Kelvin, Arizona.

WILBUR A. HENDRYX of Denver is at New York.

HOWARD D. SMITH has gone to Oroville, California.

J. D. IRVING has gone to Nevada for the summer.

BARON MANNERHEIM, of Sweden, was in San Francisco.

E. N. LOWE has been appointed State Geologist of Mississippi.

F. LYNWOOD GARRISON has gone to Arizona from Silverton, Colorado.

O. H. FAIRCHILD is in Arizona examining properties for Eastern interests.

P. H. REARDON, of the Compressed Air Machinery Co., San Francisco, is at New York.

DWIGHT E. WOODBRIDGE was in San Francisco and has gone to Steeplerock, New Mexico.

J. MORGAN CLEMENTS has moved from 15 William street to Suite 1707, 42 Broadway, New York.

A. V. JUDSON, mill superintendent for the Soledad Mining Co., at Mojave, California, is in San Francisco.

HENRY F. LEFEVRE has returned to New York after a three months absence examining mines in Central America.

F. L. RANSOME, assisted by E. S. BASTIN, will study the Breckenridge, Colorado, district this season for the U. S. Geological Survey.

A. F. CRIDER has resigned as State Geologist of Mississippi, to go with the Bishop's Alabama Marble Co., at Talladega Springs, Alabama.

RALPH ARNOLD has opened an office for consulting work in the H. W. Hellman building at Los Angeles. He will devote especial attention to oil.

H. G. GILKERSON, of Telluride, Cripple Creek, and Goldfield, has recently opened an office as a mining and civil engineer in the Judge building, Salt Lake, Utah.

ALLAN GIBB has sailed from London for South Africa, where he will proceed to erect a dressing and smelting plant at the Star of the Congo copper mine, belonging to the Tanganyika Concessions, Ltd.

J. G. LAWN, who has for two years been professor of mining at the Camborne School of Mines, is returning to the Transvaal, where he will succeed Professor Orr as professor of mining at Johannesburg.

THE UNIVERSITY OF MISSOURI SCHOOL OF MINES, at Rolla, held its thirty-eighth annual commencement June 9. Thirty-two engineering degrees were conferred, and eleven in general science.

Obituary.

NORMAN COOKSON died at Newcastle on Tyne, England, recently. He was head of the firm of Cookson & Co., noted for its brand of antimony, also lead smelters and desilverizers. He was noted as a collector and grower of orchids, his collection being probably unsurpassed.

ERNEST L. FRALECK, superintendent of the Cobalt Lake mine, died of typhoid on May 27, at the age of 33 years. He was a graduate of the Kingston School of Mines, and was regarded as one of the ablest mining engineers in the camp. He was for some time connected with the Canadian Geological Survey and did much to attract interest to Cobalt.

L. VOGELSTEIN & Co. report the German consumption of foreign copper during the months January-April, 1909, as follows:

	Tons.
Imports of copper	49,323
Exports of copper	2,703

Consumption of copper 46,620

Of the above quantity, 45,026 tons were imported from the United States. The consumption during the same period in 1908 was 53,810 tons.

Alaska's growing interests are not to be forgotten by this Congress, if the present activity toward new legislation is any sign. James Wickersham, of Fairbanks, Alaska, delegate from that Territory, has come forward with a bill providing for the creation of a general assembly with the proper legislative powers, and one providing for mine inspection and inspectors. The latter bill provides for the appointment of four mining inspectors, at a salary of \$3000 each, and for making the Governor ex-officio chief mining inspector.

General Mining News.

ARIZONA.

COCHISE COUNTY.

Sulphide ore has been cut by a 65-ft. drift on the 1200-ft. level of the Denn.—The shaft of the Heffern is down 450 ft., and the company plans to cross-cut from this point. Albert Heffern is in charge of the work.

GILA COUNTY.

The Live Oak vertical shaft, which is down to a depth of 245 ft., has been in ore for the last 45 ft., that averages 3% copper.—A raise from the Gem vein on the Globe Consolidated property shows 2½ ft. of 13% copper ore. A carload of ore recently shipped to the Old Dominion smelter ran 5% copper, 35% iron, and the same amount of sulphur. Gold and silver to the extent of \$2 per ton was also shown.

Most of the work of blocking out ore, and of driving and cross-cutting on the orebody at Miami is being done in shaft No. 2 at a depth of 570 ft. A new shaft, called shaft No. 4, is being sunk and will eventually be the main one from which most of the ore will be taken, when the machinery is in place. A force of 50 men is now at work on the 350-ft. level, and between 60 and 70 tons of ore is being shipped daily. The returns from this ore are about 12%.—The Inspiration is sinking two shafts and running three tunnels to block out the orebody. The Bulldog shaft is down 310 ft. and the Joe Bush 235 ft. Both have cut sulphide ore. John D. Coplen is manager.—Work at the 330-ft. level of the Keystone has been stopped until a station is cut at 150 ft.—From 10 to 15 tons of 20% ore is being shipped per day by the Gibson Copper Co. The ore is being stoped on the 400-ft. and development carried forward on the 500 and 600-ft. levels. S. L. Gibson is superintendent.—The Arizona Commercial Copper Co. expects to have its 400-ton smelter ready for operation about August 15.

GRAHAM COUNTY.

At a special meeting of the Shannon Copper Co. it was voted to increase the capital stock from \$3,000,000 to \$3,300,000 by adding 30,000 shares par value \$10 each.

YUMA COUNTY.

The finding of oil in an old shaft near Tacna has caused a rush to that district and a large number of claims have been staked.

CALIFORNIA.

BUTTE COUNTY.

It is officially announced that the Big Blue Lead mine will resume operations on July 15. Development work has been continued with a small crew for several months and a quantity of gravel running \$3.50 to \$4 per yard has been blocked out. W. Lambert is superintendent.—The Natoma Consolidated Co. has purchased the dredges and lands of the Feather River Development Co. and is moving the shops from Dredgeville to Marysville.—The Magalia Ridge Consolidated Mines Co. is arranging for extensive work at the Durgin and Gunn properties.—The Mammoth Channel Gold Mining Co. is awaiting the shipment of a new hoisting plant for the 200-ft. two-compartment shaft. Upon its installation three shifts will be put to work. Large quantities of pay gravel are blocked out in the shaft and the 1255-ft. tunnel.—The Cape Horn Co. is blocking out gravel. Owing to lack of water no production is going on.—The Butte Creek dredge is working downstream and handling about 150,000 cu. yd. of gravel per month. It is reported that the company is contemplating the installation of a second dredge before the end of the year.—The Cohn & Gooday Co. is developing promising gravel in its property on the Cohn ranch. It adjoins the Cape Horn mine.

EDORADO COUNTY.

The Wizard mine, which has been idle for several years, is to be unwatered and reopened. D. L. Shepherd is in charge of the work.

INYO COUNTY.

The tramway of the Four Metals Mining Co. is handling

150 tons of ore per day from the Cerro Gordo mine to the smelter at Keeler. The plant was stopped for a few days to clean out the furnace which froze when the company attempted to smelt some copper ore. The furnace will be run on a lead-silver ore in the future.

NEVADA COUNTY.

Operations have started on the McDonald ranch on the slope of Banner mountain to strike the gravel channel which crosses the property. A new shaft is being sunk and the company expects to reach the channel at a depth of 250 ft., on the incline.—The Hartery mine will probably be re-opened by S. H. Dille.—Lessees in the Providence mine have broken into the foot-wall vein. This carries free gold and sulphides.—In the Home a raise is being driven to cut the Wyoming vein.—The shaft at the Oustomah has been sunk over 900 ft. Some excellent assays have been made from the ore and it is estimated that the shoot will average \$40 per ton. Ten stamps are dropping at the mill.—The Brunswick Mining Co. has purchased five acres of ground for a surface plant and will start sinking at once.

The Brunswick Mining Co. has closed a deal for five acres of the Matteson ranch and will immediately commence the sinking of a three-compartment 1000-ft. vertical shaft. C. A. Mallen is superintendent.—It is reported that a large pocket of bonanza ore was recently encountered in the Empire.—The 10-stamp Lecompton mill is running on ore from the upper workings. The pumps are steadily lowering the water in the shaft and sinking will soon be resumed.—The Prescott Hill shaft is being sunk 500 ft. from the 1300-ft. level. The mill is running on fair-grade ore from the 600-ft. and lower levels.—Fifty lessees are operating in the Champion and 27 men are employed by the company. At the mill 30 stamps are dropping.—A shaft is being sunk at the McDonald mine to cut the old gravel channel. It is down about 20 ft., and is expected to strike the channel at a depth of 250 ft. S. H. Dille is superintendent.—A small force of men is working at the Woodberry and have opened a small streak of good ore.—The gravel channel at the Posey Canyon continues to show up well and the management expects to install additional machinery at an early date.—At the Jenny Lind a small force is driving the adit. Some fair-grade gravel has been found, but the property has not come up to expectations.

PLACER COUNTY.

At the Dewey mine, under bond to Wood & Parker, a strike of high-grade ore has been made. The shaft cut a vein of 'picture rock' at a depth of 52 ft.—The Kavanaugh Co. has struck gravel in the Placer Queen and run 300 ft. across from the western rim, but has not yet found the eastern rim. The gravel is of a bluish-gray cast and carries gold. The mine is situated between Soda Springs and Robinson's Flat.—The El Dorado-Placer Dredger Co. has decided to build another dredge at the Cash Rock in place of the one swept away by the flood last winter. The new dredge will be a bucket and suction combination.—Rich ore has been cut on the 400-ft. level of the Crater mine.—The Nevada mine near Ophir is to be re-opened by L. B. Butts.

SIERRA COUNTY.

The Brush Creek mine near Mountain House is to be re-opened. A new shaft will be sunk with stations every 150 ft., and a mill with a daily capacity of 150 tons constructed when sufficient ore has been blocked out. The old shaft is down 749 ft., cutting a 10-ft. vein between walls of serpentine and granite.

Twenty men are at work at the Willoughby mine above Gold valley. The mill is expected to start up shortly.—George P. Moore has a bond on the Southworth property in Slate Castle ravine. The Glidden mine near Gold lake has been bonded to San Francisco parties. The Gold Ridge gravel mine will be opened next month. This mine was previously worked as a hydraulic proposition, but will now be operated as a drift mine. An adit is being driven to tap the gravel channel of the Hilda mine. At the Sierra Buttes mill 20 stamps are dropping, and 40 men are working in the mine.—The Keystone mine is being worked by several sets of lessees through an adit 1¼ miles long.

TRINITY COUNTY.

Wilson and Ehrmann, who have a two-year lease on the Nob mine, have cut a 16-in. vein. This will be shipped to the smelter, as it assays over \$500 per ton.—The Trinity River Mining Co. is making extensive preparations for its summer's work in mining the bed of the river above Lewiston. San Francisco engineers are installing an electric plant with 1800 hp. This will develop power for elevators and other machinery.—Paulsen Bros., Richards & Newlands have a lease on the Jacobs mine in Eastman gulch, and they are taking out good ore, which will be shipped to the Selby smelter.—The Lappin mine, at Deadwood is developing some good milling ore. A gasoline engine is to be installed for power to run the mill.—A vein from 12 to 18 in. wide has been cut in the Leas & Nicholson mine under bond to the West Point Mining Co. The ore mills from \$50 to \$60 per ton.—The cross-cut from the 120-ft. level of the Hoodoo mine cut a 3-ft. vein of milling ore.—The Blue Jacket mine cut a 2-ft. vein of ore.—A high-grade bench placer mine has been found above Waldorff crossing, on the North Fork, by J. E. Given.

TUOLUMNE COUNTY.

Ten stamps are being added to the Omega mill to handle the increased output from the mine.—A large boiler and pump have been placed at the No. 2 shaft of the Gold Ship mine near Groveland.—The machinery at the Cosmopolite mine has been sold to a company operating a property near Bull creek.

COLORADO.

GILPIN COUNTY.

Two hundred dollars per ton was the smelter return on a shipment of ore from the Alps mine.—A gasoline hoist has been installed at the Poole shaft of the Gilpin-Boulder Consolidated Mines Co. E. H. Crabtree is in charge of operations.—Work has been stopped on the Ridge mine in the Russell district till the company can install heavier machinery.—The Daisy mill in Gamble gulch is being overhauled by Burnell & Gearan to crush the ore from their Free Gold mine near Perigo.—The Lillian, Federal, and Hughes mines in the Russell district have been bonded to Eastern capitalists.

GUNNISON COUNTY.

The property of C. C. Brunner on Galena mountain will commence shipping lead ore to the smelter at an early date.—There are two shifts at work in the adit of the Mountain King mine.

LAKE COUNTY.

About 50 tons of high-grade ore has been taken out of the recent strike on the Tribune property and will be shipped to the smelter. A sample from the present working face assayed 9 oz. gold, 30 oz. silver, 3% lead, and 3% zinc. L. R. Johnston is manager.—On the Tucson mine of the Iron Silver Mining Co. a double-drum hoist to be operated with electricity is being installed. It is expected that this work will be completed during the next few weeks.—A new hoist is also being placed in the Vinnie property of the Golden Eagle Mining Co., which is working under the management of a set of lessees through the Yak tunnel.—Al Ganz and associates have secured a lease on the Progressive property north of Fryer hill. The shaft is 800 ft. deep, and lateral work will be carried forward from that point. C. W. Rogers is in charge of the work.—The Castle View mine on Carbonate hill is shipping about 25 tons of iron ore per day to the smelter.

SAN JUAN COUNTY.

The Allis-Chalmers Co. is to furnish the Intersection Mining Co. with a 5-stamp mill. A larger mill will be erected as soon as the complete treatment has been determined.—J. B. Ross, holding a lease and bond on the Silver Ledge mine near Chattanooga, has started active work on that property. The mine is equipped with a 200-ton mill.—The second dividend of 20% on the stock of the Iowa-Tiger Leasing Co. was paid on June 15. The company is shipping ore and concentrate.

SUMMIT COUNTY.

The concentrate from the Wellington amounts to two or

three cars per day.—One car per day of high-grade zinc ore is being shipped by the Country Boy.

TELLER COUNTY.

A dividend of 1c. per share was declared by the Granite Gold Mining Co.—An important surface discovery has been made on the south end of the Nightingale lode mining claim on Raven hill, by Milhoan & Mart, lessees from the Stratton estate, and ore running as high as 5 oz. gold per ton is being saved for shipment. At the depth of 30 ft. the vein fills the bottom of the shaft and is all of a shipping grade.—A carload of 4-oz. ore was billed out from the Lucky Gus No. 2 by Moore and associates, lessees on that Stratton estate property. The ore was mined from the main Lucky Gus vein at the 400-ft. level of this Bull hill property.—On a recent shipment of ore from the Mountain Beauty the return was \$24 per ton. The lessees are following a new vein intersected by a cross-cut south of the shaft.—The Isabelle mill is treating 125 tons of \$2 ore per day. The monthly clean-up amounts to about \$7000.—A rich ore-shoot is reported entered on the Victor Gold Mining Co.'s Thomas fraction, where the lessees, Milhoan & Mart, are sinking on the main Victor vein, at a point southeast of the old workings.—The South Burns Mining Co., operating on the South Burns mine of the Acacia Gold Mining Co., has cut an ore-shoot at the tenth level. This has produced several cars of ore on which the return has been from \$30 to \$40 per ton, and a good grade of ore is also showing in the bottom of the shaft.—A new ore-shoot on the Gold King vein has been opened on the northeast corner of the E. Porter Gold King mine on Gold hill. H. J. Anstie is manager.

IDAHO.

BLAINE COUNTY.

A 75-ft. drift has been run along the vein recently cut by the adit on the War Dance property. A small seam of ore was followed and a number of pockets found.

IDAHO COUNTY.

The Chilean mill at the Twin Butte mine has been so successful in crushing the ore that another one will be installed. The mill is grinding 125 tons of ore per day to 40 mesh.—The Thunder Mountain Mining Co. is to prospect its ground with a diamond-drill from the adit level.—A large body of free-milling ore is opened on the 250-ft. level of the International mine. D. Miloradovich is manager.—Three feet of lead ore has been cut on the Saradoc property south of the Dixie by the 140-ft. adit at a depth of 75 ft.—A 7-ft. vein was cut by the 400-ft. adit of the Golden Crown mine. J. R. Painter has a bond on the property.—The Buster mine has cut a good vein of ore.

KOOTENAI COUNTY.

The Spirit Lake Mining & Milling Co. cut copper ore in the face of its 103-ft. adit. A contract for 250-ft. of work in its lower adit is to be let.

SHOSHONE COUNTY.

Leo Greenough, manager for the Snowstorm Mining Co. at Mullan, announces that the shipments of ore for May amounted to 10,000 tons. The Garfield smelter at Salt Lake City and Balaklala smelter at Kennett have contracted for the ore.—The Caledonia Mining Co., operating near Wardner, is shipping 6 cars of ore to the smelter this month. This is being mined on the 300-ft. level. The shaft has been sunk to the 500-ft. level, and a skip-pocket is now being put in, after which cross-cutting for the vein will be begun.—Three cents per share dividend has been declared by the directors of the Snowstorm Mining Co., operating in the Couer d'Alene. The fiscal year will close June 30. For the 12 months the company has declared seven dividends, with the present one, six of \$45,000, and one of \$60,000.—William Squance and associates are opening the Bullion copper mine. The ore is chalcopryite carrying some silver, and is about 30 ft. wide.—The annual report of the Blue Bell Mining Co. stated that 650 ft. of cross-cuts and drifts has been run, exposing a vein of lead and zinc carbonate. To get vertically under the outcrop will require 800 ft. more work, and this will give 1500 ft. backs.—The Jack Waite property on Tributary creek is to be opened shortly.

KANSAS.**CHEROKEE COUNTY.**

A new mill, the Edith T., has been recently put into commission by the Lotawanna Co. The ore has been developed at 125 ft., occurring in a 70-ft. face running 10%, and is mostly zinc-blende with a slight mixture of galena. The plant is a double one, and only one side has as yet begun operation. The trial run has been made successfully.—A Council Grove group of men has developed a new mine on the Murphy land in Short Creek bottoms. The ore is found at 91 ft. with a face 12 ft. high.—Many sub-lessees are at work on the Short Creek land since the unwatering, and most of these are finding good ore.—The Oklahoma Mining Co. at Baxter Springs is putting shaft No. 2 into commission and is installing the necessary machinery. A rich deposit of ore has been found in sinking the mill shaft deeper and the stope will be taken up.

MISSOURI.**JASPER COUNTY.**

The feature in this district is the reviving of old properties. The Huron Mining Co. is now operating on the old Pearl C. tract from three shafts. A number of drifts have been run at the 125-ft. level, part encountering good zinc-blende and part rich silicate. The old mill on the land has been overhauled for present operation.—The Barfet Mining Co. is working the old Cardinal tract, having run drifts above the former timbers and a good tonnage of ore is being taken out. The ore is treated on a battery of hand-jigs.—Two new sludge plants are at work in the camp, the A. W. Grannis plant on the tailing accumulated from the custom mill near the Frisco railroad and the mill recently built on the Kalitan ground.—To the east of Sucker Flats the Alben tract is the scene of a strike at 210 ft., continuing to 246 ft. Contrary to the usual conditions in this district the zinc ore is found on top and the galena below.—The News-boy mine has been re-opened and a mill of 150 tons daily capacity completed.—The Missouri Mule is being opened north of Webb City, the same run being found which is worked on the Red Dog adjoining. A shaft is being put down north of the old mill and an inclined tramway is to be built.—In the same camp the White Dog has found a run of sheet lead 6 ft. thick below the former drifts.—Several mills are ready to operate on ore from leases in the sheet-ground camp west of Joplin.—M. G. Esterbrook is making improvements at the Rabbit Foot mine in Central City to work a body of 4% ore.

NEWTON COUNTY.

In the Little Boss at Granby a 20-ft. face of rich silicate and lead with a small percentage of zinc-blende has been opened.—On the same land Goade Bros. have developed a lease until a mill is needed.—The old Delta mine at Spring City is to be re-opened by a new company, as the former one forfeited the lease. A new shaft is being sunk to the deposit which will also provide better ventilation, and plans are also under way for the building of a larger and more modern mill.—In the same camp to the east of the lake the Microbe Mining Co. is erecting the old Dutch Mike mill moved from the Blendville camp.

MONTANA.**FLATHEAD COUNTY.**

The Silver Crown Mining Co., operating a group of claims on Granite creek, 10 miles from Libby, has shipped 18 tons of silver, lead, and gold ore to the Tacoma smelter.

GALLATIN COUNTY.

A fire at Storrs, 12 miles east of Bozeman, completely destroyed the coal washer of the Washoe Copper Co.'s plant. The plant and mines were recently leased to J. P. Reins, of Butte.

NEVADA.**ESMERALDA COUNTY.**

The shaft of the Nancy Donaldson is down 80 ft. and the company has installed a hoist for deeper sinking and lateral development.—The framework for the plant of the National Ore & Purchasing & Reduction Co. at Rawhide is nearly completed. Many lessees are holding their ore to save transportation expenses.

HUMBOLDT COUNTY.

The Florence lease on the property of the Seven Troughs Mining Co. cut a vein of copper sulphide carrying a high percentage of silver in their 200-ft. cross-cut from the shaft.

NYE COUNTY.

The shaft on the Rickard-Garberg lease is down to the 275-ft. mark. In the lateral work at the 160-ft. level 30 ft. of vein matter has been proved in place, some 4 ft. of this assaying \$25 or \$30 per ton.—The Pioneer Leasing Co., of Rhyolite, announce that they will pay their first dividend, probably 5c. per share, before the end of this month.—The Montgomery-Shoshone has 5000 tons of high-grade ore opened on the 500-ft. level.—The Tonopah Extension Mining Co. has broken ground on its mill-site. The mill is to have 30 stamps.—The Jefferson Mining Co. cut a body of ore in a 70-ft. winze that assays 7000 oz. silver per ton.

Three hundred men are working at Pioneer. Fifteen gasoline and two electric hoists are in commission.—In the Tex Rickard property a stringer of ore about 4 in. wide has been struck near the 200-ft. level, that carries ore assaying \$400 per ton. About 500 sacks have been extracted. A drift is being driven from the 200-ft. level to develop the shoot.—The Pioneer lease has installed an electric hoist at the 215-ft. point in an 80-ft. winze. A carload of ore valued at \$12,000 was recently extracted at this level and shipped to Goldfield. The lease is shipping at the rate of

Hooligan Hill, Rawhide.

90 tons per day.—The Engineers lease on Pioneer has a shaft down 100 ft. and is installing a double-drum electric hoist. Three shifts are working. A 20-ft. vein of milling ore has been cut by the shaft.—The shaft at the Savage lease is down 145 ft. and a 15-ft. cross-cut has uncovered a vein of \$12 ore.—The Mayflower mill is operating steadily on good-grade ore. The May clean-up amounted to \$12,000.—The Jefferson mill at Round Mountain has been completed and the plant will be placed in commission within two or three weeks. It is expected that its operation will result in the working of several mines in the district that are now idle owing to lack of milling facilities.—Owing to a war over the water-right between the Daisy and Hydraulic companies, the pipe-line company has refused to carry the water for the two mills. As a result the Daisy and Sphinx mills are closed. In order to avoid extended litigation the Daisy Co. is arranging to construct its own pipe-line.—The Round Mountain Co. has struck a pocket of remarkably rich ore. Several large nuggets have been extracted.—The Johnnie Mining & Milling Co. is producing at the rate of \$15,000 per month. P. E. Mitchell is manager.—The placer mining excitement continues and a majority of the claims are making good. In many cases the unusually high costs of working the properties materially offsets the richness of the gravel.

WHITE PINE COUNTY.

The Success mine at Ely is being unwatered and will commence shipping to the Salt Lake smelter.

NEW MEXICO.**LINCOLN COUNTY.**

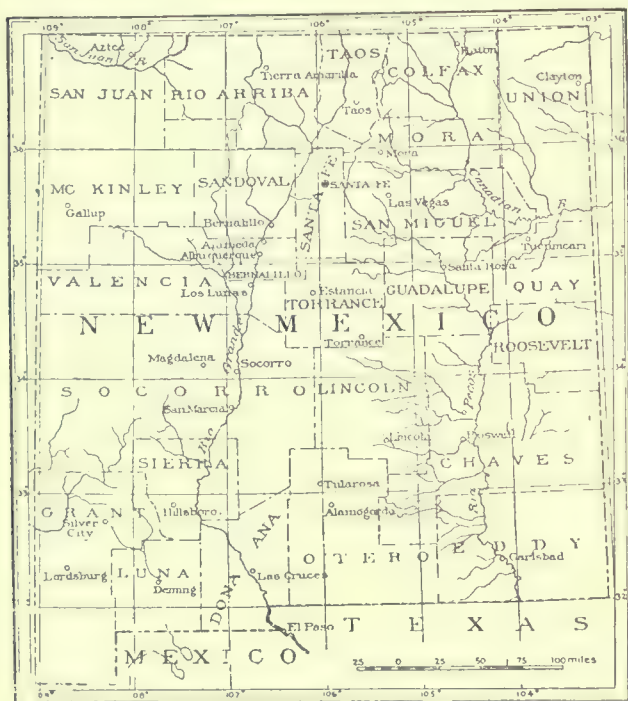

M. Wertman, who has a group of six claims in Oscuro district, is driving a tunnel on the Copper Foothill lode and is now in 300 ft. on a vein of copper ore which also carries silver and lead. In drilling for water on the outskirts of the district Robert Ross and S. W. Whitmire passed through 4 ft. of coal at 60 feet.

OTERO COUNTY.

J. C. Dunn, who has a group of five claims three miles from Alamogordo, is down 100 ft. and has 6 ft. of \$12 gold ore.—A force of 60 men is at work on the Bent property on Tularosa creek. The mill is to be added to and the property worked on a larger scale.—The new sampling ore-bins at the Orogrande Smelting works are now completed and the ore crusher has been put in place. The carriers are being installed and connections made which will make this one of the best sampling plants in the territory. When completed the plant will be able to take care of two cars per hour. No definite date has been set for blowing in the smelter, but men are now out buying ores which are to be brought in as soon as the sampling plant is ready and the bins will be filled up.—G. E. Moffett and associates have resumed work on the Monarch and are now making a raise from the main drift from the 200-ft. level for the purpose of intersecting an old winze made from the 100-ft. level.—The Treasure Mining Co. is taking out some high-grade silver and copper ore.

SOCORRO COUNTY.

The Kelly mine is now in active operation, the present output being 35 to 40 tons of sulphide ore per day, which

Map of New Mexico.

is mined from the fifth and lower levels. The portion of the mine east of the Paschal shaft and from the fourth level up, is being operated under a lease by C. T. Brown, who is shipping from 40 to 50 tons of oxidized zinc ore per day.—The Tri-Bullion Co. is completing its roasting and magnetic plant, to be operated as an auxiliary to the wet mill, which will be run on the lower-grade sulphides. The higher grade of that class of ore is shipped to the zinc smelters in the gas belt.—The oxidized zinc ore produced by the Brown lease is under contract to the Prime Western Spelter Co. at Iola, Kansas.

TORRANCE COUNTY.

A new discovery has been made around Monzano mountain, west of Mountainair. The finding of rock that assayed gold and copper in the ballast of the Belén cut-off on the Santa Fé railroad, led to the staking of a number of claims, at the place where the ballast was obtained, and surface prospecting has shown several veins that assay high in gold and copper.

OREGON.

BAKER COUNTY.

T. S. Kennesly has bonded the Double Eagle mine adjoining the Gold Coin and will work the two groups this summer.

GRANT COUNTY.

The average width of the No. 3 vein recently cut in the Buffalo-Monitor is about 2½ ft. The vein has a soft gouge on each wall and the gold predominates over the silver. The ore is being sorted preparatory to shipping the high-grade to the smelter.

JACKSON COUNTY.

The Electrical Gold Dredging Co. has purchased the property of D. P. Blue on Kanes creek and have installed a 42-ton steam-shovel. The company owns 160 acres of ground.

LAKE COUNTY.

A good vein of milling ore was cut on the Goldberg Butte property. The company is running a drift on the vein and an adit to cross-cut the west vein on the property. E. O. Kelly is superintendent.—The Jumbo Chief Co. is driving an adit to develop its property.—A group of California capitalists have taken a bond on the claims adjoining the Jumbo Chief.

UTAH.

BEAVER COUNTY.

The vertical shaft of the Majestic Mines Co. has cut an orebody that assays 22 oz. per ton of silver and 14% lead. The ore was found at a depth of 400 ft. and 175 ft. west of the ore cut by the inclined shaft. Alex. J. Moffatt is manager.—A drift of the Utah Gold & Copper Co. is following an 8-ft. vein of lead-silver ore.—The shaft at the King David mine cut an orebody at a depth of 300 ft. The ore is an iron sulphide carrying copper and silver.

JUAB COUNTY.

The Uncle Sam Consolidated Mining Co. is again shipping to the smelter at Tintic. C. C. Griggs is superintendent.

SALT LAKE COUNTY.

The winze from the fourth level of the Utah Apex mine is down 100 ft. Robert S. Oliver is manager.

UTAH COUNTY.

Arrangements have been completed whereby the Knight interests secure control of the Mountain Lake Extension property, which is on the divide between Little Cottonwood and American Fork mining districts. The property consists of 19 claims and is equipped with a boarding-house, blacksmith shop, snow-sheds, cars, rails, and tools. A cross-cut is being run to cut the veins that are said to traverse the Mountain Lake, Mountain Lake Extension, and Mineral Flat properties. The adit is now in a distance of over 850 ft. A 200-ft. shaft has also been sunk and something over 80 ft. of winzes. Louis A. Christink is the superintendent.—Three companies, the Colorado, Iron Blossom, and Sioux Consolidated, will pay dividends this month. Colorado, on June 21, will pay 8c. per share, or \$80,000, to stockholders of record on the 15th. Iron Blossom will pay 8c. per share, approximately the same amount, on June 25, to stockholders of record on the 20th. Sioux will pay 7c. per share, or \$49,000, on June 20, to stockholders of record on June 15.

WASHINGTON.

CHELAN COUNTY.

The Halden mine is developing a 40-ft. vein of copper ore. More than 3000 ft. of drifts and cross-cuts have been run.—Harry Krollpfeiffer, manager of the Chelan Consolidated Mining Co., announces that work on the adit in the Leavenworth district will be resumed soon under the superintendency of F. C. Buckingham.

FERRY COUNTY.

The lessees of the Lone Pine claim, one of the Pearl Consolidated group, are employing 11 men and have shipped four carloads of ore. The shipments from the Surprise claim, of the same group, have been reduced to three carloads per week, the smelters being unable to use more for the time being.—The Ben Hur mine has been bonded to a leasing company, which has started work with four men.—The Colville Mining & Smelting Co. has resumed work on the mines at Park City, with Herbert M. Lycett as manager and William M. Crummer as superintendent. The machinery for the smelter is on the ground, and, it is thought, will be in running order some time in August.—The Belcher

Mining Co. has made excellent progress at the Belcher mine. The tramway from the mine to the ore-bins at the head of the Belcher Mountain railway has been completed, enabling the landing of six tons of ore to the bins, over a double track, every five minutes. A raise has been put up from the No. 3 adit level toward the No. 2, 80 ft. in ore. Another raise has been put up from the No. 2 adit level 145 ft., the last 30 ft. being in carbonate ore, carrying some gold and assaying about 40% iron. It is estimated that the body is 60 ft. wide and contains about 40,000 tons. The repairs to the Belcher Mountain railway have been completed, and 40 tons of iron sulphide ore has been shipped to the Granby smelter at Grand Forks, B. C., and 20 tons of carbonate ore to the Trail smelter at Trail, B. C. Bruce White is in charge of the work.

OKANOGAN COUNTY:

Arrangements are in hand for the building of a mill at the Ruby mine, at the base of Mt. Chopaca, near Night-hawk, for the purpose of introducing an electro-chlorination process. The development of the Ruby mine is such that an unlimited quantity of medium and low-grade ore has been exposed. The mine has produced considerable high-grade ore, the shipping returns being over \$300 per ton and paying nearly all the expenses of opening the mine.—The workings of the Golden Chariot mine, on Kruger mountain, have reached a vertical depth of 200 ft., and a drift is being driven on a 6-ft. vein, following a pay-streak from 8 to 18 in. wide. Two carloads of ore have been shipped to the smelter.—The face of the long bore of the Palmer Mountain Tunnel & Power Co., on Palmer mountain, shows a change in the formation; the rock is softer and water is flowing in freely. A small stringer of quartz shows strong indications of copper.—Work has been resumed on the Rainbow group, on Copper mountain, in Meyers Creek district. New living quarters are to be erected and the extraction of ore for shipment started when the wagon-road is completed. The group consists of the Rainbow, Texas, and Mexico claims, which have been opened by 540 ft. of adits and drifts and about 150 ft. of shaft work. The ore yields copper and gold.—Ore is being mined and milled at the Poland-China mine.

STEVENS COUNTY.

The Border Mining & Milling Co. has contracted with the Kettle River Lumber Co. for a tract of land adjoining the Beecher townsite, and has also contracted for the purchase of 350,000 shares of the stock of the Beecher Gold Mining Co.—The double-compartment shaft on the Second Thought mine is down 50 ft. and has cut a vein between well defined walls.—The adit on the Trojan mine is in about 550 ft. and has intersected 10 ft. of vein material, separated by talc from the walls. The foot-wall is of andesite and the hanging of granodiorite. A drift will be started on the vein, and the adit will be extended about 200 ft. farther to cut the main vein. The face at present is at a vertical depth of about 400 ft.—The Michigan Mining Co. has encountered ore in the adit on the Chicamun claim which assays from \$120 to \$140 in gold per ton.—A new strike of galena and chalcopryite has been made in the Easter Sunday mine at a depth of about 25 feet.

The Arlington mine at Ruby has resumed operations. The mine is developed by a shaft and a cross-cut to the 200-ft. level, and on that level drifts were run on the vein for about 700 feet.

WYOMING.

UINTA COUNTY.

A new oil district has been opened near Kemmerer near the Oregon Short Line. Two California companies are operating there at present, the Fresno-Wyoming and Fresno Uinta Oil companies. All the available land around Kemmerer for miles has been located and all of the companies operating in the field have large holdings in that locality.

CANADA.

BRITISH COLUMBIA.

The largest copper-furnace in the Dominion of Canada, 42 in. by 25 ft., was blown in by the Consolidated Mining & Smelting Co., at its Trail smelter in the early part of this

month. This gives the company four large copper-furnaces, with a capacity of 1800 tons per day. Mechanical feeders are being installed on the large lead-furnace. This makes as high as 98 tons of bullion in 24 hours and the refinery is producing as high as 75 tons of pure lead per day. The Consolidated company has taken a bond on the Alice mine near Creston.—The Dominion Copper mines at Phoenix have been purchased by Charles Hayden, of New York, for \$261,500.—The latest strike on the Golden Belle mine at Sheep Creek has shown an assay value from a large sample of \$10.25 per ton. The Kootenay Belle mill and mine at this camp is again under operation by J. L. Warner and his associates.—The Granby Co. is making arrangements to start work on its Gold Drop property in Phoenix camp, secured several months ago. The mine is virtually a quarry, and will employ between 150 and 200 miners.

The Blue Bird mine shipped 30 tons of rich ore during the past week, while the Centre Star group and the Le Roi No. 2, Ltd., sent average shipments to the Trail smelter. It is rumored that work will be resumed at the Le Roi shortly.

ONTARIO.

The Beaver Consolidated Co. cut two veins of calcite and quartz with their diamond-drill.—On the Peterson Lake lease of the Little Nipissing a good ore-shoot has just been cut in the raise from the 160-ft. to the 100-ft. level. The vein is 4 to 8 in. wide of 3000 to 4000 oz.—The Wettlaufer, of the South Lorrain district, has started their new 6-drill compressor. The development work at this mine has paid for the equipment. Frank C. Loring is consulting engineer.—A 5-in. vein of calcite, cobalt, and silver was cut by the Gavin-Hamilton Co. The company will cross-cut and drift on the vein at the 125-ft. level.—The No. 4 vein on the fourth level of the Big Pete mine in the west drift has widened out to 20 ft. of good milling ore. J. W. Young is superintendent.

The shaft of the Ophir Mining Co. at Cobalt is down 30 ft. The company has erected a head-frame and installed a power-hoist. It is the intention to sink 250 ft. and cross-cut to the vein, which is a few feet from the shaft.—The Campbell Crawford Mining Co. and the Cobalt Silver Prince are to resume work shortly on their properties on the west side of Cross lake.

MEXICO.

MICHOACAN.

The Santo Niño gold mine in the Coalcoman district, about six hours from the Pacific coast, has been purchased by A. R. Downs, his son E. R. Downs, and Thomas L. Woodruff, manager of the Pacific Timber Co. The old workings of the mine are now being cleaned out and new development work will soon be commenced.

NUEVO LEON.

Oil properties in northern Mexico are attracting more and more attention from investors in the United States. It is said a thorough investigation of many leases held by Monterey people is being made by representatives of large northern corporations that expect to enter the oil-producing class in Mexico in the near future.

SONORA.

The Transvaal and Belen mines near Moctezuma are working large crews on development work. This will continue until the Southern Pacific railroad reaches that camp.—The smelter of the Promontorio is ready to start as soon as the railroad can haul fuel and supplies.—The Monte Cristo is shipping ore that runs 700 oz. silver per ton.

TEPEC.

Several carloads of reduction machinery for the Tena mache mines, north of Santiago Ixcuintla, were recently unloaded at the Pacific port of San Blas, and some of the machinery is now being taken across country to the property. The Tenamache plant will have a capacity of 50 tons per day, and will be one of the most complete in that part of Mexico. The Tenamache mines are owned by the Tenamache Mining Co. of which W. R. Ramsdell is president.

Special Correspondence.

LONDON.

Mount Lyell.—Zinc Corporation.—Dunderland Iron Ore.

The cable advices relating to the results at the Mount Lyell Mining & Railway Co., Tasmania, for the half-year ending March 31, has just been received. The most noteworthy point is that the marketing of the output of copper still gives trouble. As long as the black copper is shipped to the United States for refining and disposal this trouble will last, at least during dull times. One day, no doubt, the new electrolytic works at Port Kembla, New South Wales, which now deals with the Mount Morgan copper, will be available for the Mount Lyell output. The report shows that the 852 tons reported unsold on September 30, 1908, were subsequently disposed of at an average price of £61 6s. per ton. During the six months ending March 31 last the output was 4387 tons of blister copper, containing 4331 tons of fine copper, of which 3243 tons were sold at an average price of £61 17s. 6d.; and 1088 tons carried forward unsold. In addition, the blister copper contained 6856 oz. of gold and 366,706 oz. of silver. The ore treated during the half-year was 134,720 tons from the Mount Lyell mine, and 67,318 tons from the North Mount Lyell, a total of 202,038 tons, averaging 2.64% copper, 1.86 oz. silver, and $\frac{3}{8}$ dwt. gold per ton. In addition to the ore treated at the smelters, 13,169 tons were sold to chemical works for the sulphur content. The net profit for the half-year was £126,158, after making due allowance for depreciation, development, and taxes. Dividends for the half-year at the rate of 1s. 9d. per share absorbed £105,000. The manager reports that the cost of producing blister copper was 15s. 3d. per ton of ore, which was 3d. per ton more than during the previous six months, the increase being due to the extra consumption of fuel. The available ore reserves on March 31 are given as follows: At the Mount Lyell mine, available by open-cut, 620,166 tons, averaging 0.6% copper, 1.93 oz. silver, and 0.86 dwt. gold; available by underground mining, 2,613,945 tons, averaging 0.52% copper, 1.97 oz. silver, and 0.5 dwt. gold; at the North Mount Lyell, 713,936 tons, averaging 6% copper, 1.33 oz. silver, and 0.1 dwt. gold per ton. The ore reserves at the North Mount Lyell have been increased during the half-year. The super-phosphate industry is becoming an important branch of the company's business and high-grade iron pyrite in outlying districts is being mined for this purpose.

At the meeting of shareholders of the Zinc Corporation held recently, H. C. Hoover, one of the directors, to whom is due a large share of the credit for the success of the plant, gave some further interesting details regarding the Elmore vacuum process. He mentioned that new furnaces have been erected for the purpose of de-oiling the Elmore concentrate. The first furnaces emitted undesirable fumes, and the new ones are provided with scrubbing towers to mitigate the nuisance. Continual study is being made of the problem of dressing the Elmore concentrate into zinc and lead products, for the effective reduction of lead in the zinc product has a very important bearing on the prices received by the corporation. Mr. Hoover indicated that further improvements were being effected in this direction, and that the production of lead concentrate would before long be substantially increased. He also spoke of the nature of the material which was at the disposal of the corporation, a subject which is of importance, owing to adverse critics saying that the resources of the corporation were limited. At the present time the plant is working on the dump purchased from the Block 10 company, which is admittedly the best and of most uniform material. In determining the capabilities of the flotation processes, it was only natural that the most suitable material should be treated first. Now that a commercial aspect has been given to the process, and its nature ascertained in detail, there is every reason for expecting that it can be equally well applied to other dumps. The Block 10 dump runs about 20% zinc, and there is sufficient left to last for nearly three years. The next dump of

importance is that bought from Broken Hill South Blocks, of which there is approximately a million tons averaging 18% zinc. This difference of 2% zinc is naturally an important item, but increasing efficiency will be expected to make up for the decreased content. The corporation also owns dumps bought from the British Broken Hill, and the Block 14 companies, amounting to about 600,000 tons. These dumps are more irregular in character, some parts being richer in zinc than that now treated, and other parts much poorer. Also the nature of the gangue matter varies a good deal. Recently in writing of this corporation's business, I mentioned that an additional unit of Elmore vacuum plant was being erected for the purpose of experimenting on other material. The duty of this plant is to ascertain the most profitable way of mixing the material in these various dumps. Altogether the corporation has enough material to last for 11 years.

For many years the vicissitudes of the Dunderland Iron Ore Co. have been a sort of perennial wonder in the English metallurgical world. Started to treat low-grade hematite ores in Norway, by means of the Edison dry-crushing and magnetic separation process, as yet unproved, the company spent enormous sums in erecting a colossal plant. Year after year one practical difficulty after another cropped up, and large additional sums had to be raised to effect alterations. Finally, last year, the dust difficulty and the low extraction put a stop to operations, and the company went into bankruptcy. David A. Bremner, the manager, reported to the trustees that by the expenditure of another £120,000 or so, the worst defects might be remedied, but he was not at all sure that even then the operations could be conducted successfully. It was therefore decided to approach Dr. Grondal of Stockholm, Sweden, whose process for concentrating magnetite wet has already proved a success, as is generally known to your readers. The Dunderland company owns others besides the hematite deposits which are now being worked. These are of magnetite, and it is proposed to develop them. It is recommended that 10 units of Grondal plant be erected, of which 9 are to be used on the magnetite. The other one is to be used in an experimental way on the hematite ores, in conjunction with a furnace which will render the hematite magnetic. These 10 units should produce 400,000 tons of concentrate per annum. The trustees are recommending the raising of the necessary capital for installing the new plant. Whether success will eventually come to the company remains to be seen, but it is evident that the prestige of Edison as an inventor has once more had a rude shock.

NEW YORK.

International Smelting.—Copper Stocks.—Miami.

Strenuous efforts are being made to create interest in International Smelting stock. Influential brokerage houses in New York are mailing out optimistic accounts of the outlook. Stock of the par value of \$10,000,000 is outstanding. The directors propose meeting early next month and declaring a substantial dividend. The amount has not yet been determined, but it will be either at the rate of 8 or 10%. Immediately after that the stock will be listed on the New York Stock Exchange, so that the underwriters may be able to distribute it profitably to the public. The directors' plans regarding fresh purchases of mines and smelters have been considerably interfered with by the death of H. H. Rogers. Some of the options to purchase, however, will shortly be exercised. Steady improvement is noticeable in the copper market. The stocks on hand in the Eastern centres on June 1 were officially estimated at 169,800,000 lb., as compared with 183,198,073 lb. on May 1, 173,284,248 lb. on March 1, and 122,357,266 lb. on January 1. Since January 1 copper stocks in the East have increased by 47,490,975 lb. There are no estimates available for the stocks held by the mines and smelters, but as production is increasing steadily in most places, it appears probable that these are also increasing. Some producers, however, report having been able to place a large part of their stocks at current rates for future deliveries. It is semi-officially reported that the United Metals Selling Co.

has succeeded in placing with consumers a large part of the Amalgamated Copper Co.'s copper stocks for July and August deliveries. Considerable interest is being manifested as to the successor of H. H. Rogers in the management of various copper properties. At the recent meetings of the International Smelting, Amalgamated Copper, Anaconda Copper, United Metals Selling, and other subsidiary concerns, Mr. Rogers' technical advisors were elected to the positions he formerly held. No intimation was given as to the person, or persons, who will have the actual active management. We learn, however, from good sources, that J. P. Morgan will become active in copper matters, and that he will be assisted by William Rockefeller.

In view of the possible advance next winter in the price of copper, Boston mining operators and investors are giving attention to the acquiring of copper properties, with a view to the subsequent promotion. Options have been taken over a large number of copper mining claims in Arizona, Utah, and Montana, and experts are now reporting on the properties. Reports from the Corbin camp, Montana, are very favorable.

The directors of the Miami Copper Co., Arizona, report that the ore blocked out is estimated by the manager to amount to not less than 14,000,000 tons. The company is erecting a smelter and an extensive milling plant near Globe. The mill will have a capacity of 2000 tons. The company's stock has been largely traded in on the Boston and New York curb markets for several months past, and is one of the most popular of recent issues.

MEXICO.

Extensive Drought.—Railroads in Western Chihuahua.—Santa Eulalia.—Thomas Cole's Investments in Rayon District.

The unusual dry spell through which Mexico has been passing this year has had a most disastrous effect upon all industries throughout the Republic, and mining interests have suffered materially. Many properties have had to close down for lack of water for the mills and for other purposes, and others have been unable to ship ores because the freighters have not dared to take their animals out on the roads where there was absolutely no water. As a rule there are some early spring rains which replenish the supply and enable one to tide over until the regular rainy season, but this year the spring rains have been woefully lacking, and scarcely any part of the country has been favored. In some States the drought has been partly broken during the latter part of May and the first of June. This has given great relief, but so far the State of Chihuahua has been but lightly blessed in this particular, and the question is still serious. The smelters as well as mines have been close to a shut-down. The feeling now, however, is that the worry cannot be greatly prolonged, for the last days of June will bring rains in some districts, and the rivers will carry the waters and relief to others. Much new work is planned for the fall months in different parts of Chihuahua. Chief among these is the one projected by F. S. Pearson and his Canadian associates, including the purchase of the Chihuahua & Pacific and the Rio Grande, Sierra Madre & Pacific railroads, with their extensions until connected, and thence west to the Yaqui river and the Pacific; the building of a railroad from Monclova, State of Coahuila, to the city of Chihuahua; the absorption of the timber interests of the Sierra Madre Land & Lumber Co., and the resumption of work there; and the taking over of one or more of the power-concessions on the Conchos river, certainly that known as the Ginther concession about 15 miles above Santa Rosalia. The impounded water there will give from 30,000 to 40,000 hp., which will be distributed among the mining camps of Santa Barbara, Parral, Almoloya, Naica, Santa Eulalia, and possibly others in the State of Chihuahua, and with the waste waters it is expected to irrigate some 200,000 acres of bottom lands. On this it is expected that work will begin in 60 days.

Next in importance is the work of the American Smelting & Refining Co., whose two trams in Santa Eulalia will soon be connected and working together, when the production of

ores will be increased to 500 tons per day. This will call for the immediate addition to the company's Chihuahua smelter, as contemplated, of equipment which will change the plant from three stacks of 450 tons daily capacity to five stacks of 750 tons. The additions to the power-plant have already been ordered. The repairs to the San Toy Mining Co.'s tram, which lost its terminal by fire in the early part of the year, have now been completed, and shipments will be greatly increased. During this temporary curtailment a large orebody recently struck in the company's property has been thoroughly opened, and it is now stated that there is here a showing of 2,000,000 tons of \$60 ore, of the lead-silver carbonates so coveted by the smelters.

On the Carmen-Negrita group of 19 pertenencias in the Santa Eulalia district, purchased from the Prieto estate this year by Walter Laclacklen, one of the large holders in the San Francisco del Oro of Santa Barbara, Chihuahua, preparations are being made for sinking a shaft. It is the purpose to sink 1000 ft. before any lateral development is attempted, but the location of this property practically in-

Part of Chihuahua.

sure a successful outcome. At El Cristo, in Santa Eulalia, development is being carried on, but no shipments are being made because of the low price of the metals. From the Chihuahua Mining Co., the Potosí Mining Co., and the Buena Tierra, there has been no curtailment of production, nor at the Reina de Plata. The Parcionera will be again placed on the shipping list within the next month or two.

It now appears that the examinations made of some of the W. C. Greene holdings by L. D. Ricketts and James H. Kirk about six months ago, were for Thomas Cole, and that he, together with Duluth friends, have taken over the Belén, Refugio, and adjoining smaller properties near Ocampo in the Rayón district, and will resume operations before the end of the present year.

JOHANNESBURG, TRANSVAAL.

Underground Breaking and Sorting.—South Reef in Turf Shaft.—Engine Drivers' Demands. — Estimated Output for 1909. — Carbonaceous Matter in Lime.—Technical Education.

Now that the proposed erection of great central electric generating stations gives promise of much power, cheaper and well adapted for underground transmission, the question of underground crushing and sorting is receiving close attention. About 15% of the rock hoisted on the Rand (that is, as much of the practically barren quartzite, unavoidably broken with the conglomerate, as can be safely eliminated) is sorted out on belts, rotary tables, or floors, and sent to the waste dump. Apart from this a small percentage is picked out in the stôpes and used for packing. The scheme now in favor is to sort in the levels or near the shaft-bins, underground, the ore to be run through a crusher, washed, and sorted from belts in the ordinary way. The waste

eliminated would be used for packing and save much timbering expense. There would also be a saving in hauling expenses, proportional to the percentage of sorting effected. In a paper read recently before the Transvaal Institute of Mechanical Engineers, W. Calder took rather an optimistic view in assuming 20% underground sorting. The work would probably not be performed as efficiently as on the surface, and the disposal of so large a quantity of rock in old stopes would be costly, especially in mines of low dip. The amount of rock would moreover largely exceed actual requirements for mine support. The scheme of first-stage crushing and sorting at central stations is likely to be most favored.

The reef cut at 3815 ft. in the vertical shaft of the Village Deep (Turf Mines portion) is undoubtedly the South Reef, although a poor banket bed cut 60 ft. higher up was at one time thought possibly to represent that body. As the grade is quite payable, the strike is highly satisfactory and provides further proof of the persistence of the gold content in the reef series at great depths in the Central Rand. In appearance the reef looks remarkably 'healthy', with abundant white pebbles of good size (small pebbles are usually associated with poor grade) and much pyrite. The gold is characteristically erratic in distribution, adjacent samples of a few inches in width jumping perhaps from 20 dwt. to 1 dwt., but it is nevertheless in very fine particles. Rapid changes in value, from foot to foot, is a typical feature of South Reef.

There is a decided scarcity of good engine-drivers upon the Rand today, and an increase in the standard rate of pay from 20s. to 22s. 6d. per 8-hour shift is being asked. The majority of the mines appear willing to make some concessions, even though not to go to the full extent of the demand. As a class, the engine-drivers are on a much higher plane than the miners, in whose strike of 1907 they refused to join. Consequently their demands are being met in a most sympathetic spirit, and no trouble need be anticipated. In some quarters it is suggested that the best solution of the present difficulty (a natural sequel to the scarcity of drivers and the growing demand for skilled men) would be to pay the 22s. 6d. per shift standard to all drivers on main-hoists, but to have them 'lay-off' on Sundays. Although there is no hoisting on Sundays, excepting in connection with emergency work or privileged development, the men put in a full shift cleaning up and at other light work in the engine room which could be accomplished in a few hours by one of the fitters.

The gold outputs declared for the last three months have been disappointing. The excessively heavy rains early this year had a serious effect on production, and the industry has not yet completely recovered. Returns to date stand as follows for the whole Transvaal, of which the Rand accounts for 97 per cent:

	Fine ounces.	Value.
1908	7,052,617	£29,957,610
1909:		
January	615,113	2,612,836
February	565,218	2,400,892
March	607,500	2,580,498
April	607,101	2,578,804
	2,394,931	£10,173,030

This rate of production for 1909 is little over £30,000,000 per annum, whereas £32,000,000 or £33,000,000 have been anticipated as the yield for the current year. In view of mill extensions under completion and new mines preparing, it is still reasonable to hope for the accomplishment of this record. The chief producers in April were the following:

	Stamps.	Yield.
East Rand Proprietary.....	820	£224,346
Robinson	210	106,346
Simmer & Jack.....	320	98,917
Robinson Deep	300	84,428
Ferreira Deep	160	78,481

The working costs of the Robinson and Simmer & Jack remain the lowest on the field, at \$3 per ton, including development. Cyanide managers have good cause to be thank-

ful for the ventilation of the question as to the presence of appreciable quantities of carbon in our commercial lime, and its deleterious influence as a gold precipitant in the works. There is ample limestone of the best quality in the country, but it is essential to introduce the Hofmann kiln or other efficient plant.

In one of his articles, entitled 'How it Strikes an American' (in your issue of April 3), T. Lane Carter refers to the progress of technical education on the Rand and to the night schools, "where the miners and apprentices may learn something of the theory of their work." Since Mr. Carter's departure, a noteworthy development has occurred in the latter connection by the institution of a course of mining lectures, delivered by Prof. John Yates, at various points along the reef. The distance from one end of the double or treble line of working companies to the other being over 40 miles, it is easy to understand that difficulties in the way of attending evening classes were insuperable to many. The experiment of 'taking the lectures to the men' has proved very successful, and the roll of attendance exceeds 200. Of these, about a third may be called 'working miners'—men of practical experience anxious to broaden their knowledge so as to be prepared for the Governmental examinations—and the rest, samplers, surveyors, and others of the official class, who have not had the benefit of a university training. A genuine effort is being made upon mines to increase the number of apprentices, especially in the shops. The industry is not even yet sufficiently settled to make the system popular, since boys find so many opportunities of slipping into well paid jobs without an irksome period of tuition. The practice can only be developed gradually, and because it has not already shown results comparable with conditions prevailing in Europe and America, there are some immoderate critics who proclaim that the mines are playing with the question.

TORONTO, CANADA.

May Cobalt Output — Temiskaming & Hudson Bay. — Kerr Lake. — Silver Lake.—McKinley Darragh.—Gowganda.

May proved a record month for Cobalt ore shipments, which aggregated 2508 tons, as compared with 2492 tons in April. There were 18 mines on the list, the principal shippers as usual being La Rose with 575 tons, and Nipissing with 518. Shipments were well maintained during the earlier part of the present month, notwithstanding which the market for Cobalt stocks continues depressed. The feature of the present week has been a break in Temiskaming, which has lately been on the down-grade, owing to the general impression that the 6% quarterly dividend will not be maintained. The stock, which at the beginning of the year sold as high as 178, dropped to par a few days ago, but has since rallied a little. The effect has been to depress the entire market, except a few leading issues. One of the most important parties which has inspected the camp for some time came recently, in charge of Wm. Starr Bullock, of New York, their special object being an inspection of the La Rose mine. Wm. E. Hidden, who accompanied the party, expressed the opinion that production would continue for 50 years. The shareholders of the Temiskaming & Hudson Bay have voted to organize a holding company, increasing the authorized capital from \$25,000 to \$3,500,000. Each stockholder will receive 400 shares of new for every share of old stock, and 400,000 shares of the new issue will be left in the treasury for building a concentrator and developing the property. The Kerr Lake reports its May output at 220,000 oz. silver. The main drift on No. 7 vein at the 150-ft. level was driven 72 ft. on a continuous pay-streak of high-grade ore. A new vein showing high silver content has been struck in trenching on the east side of the property. The Silver Queen, which has been under a cloud for some time, has a glimpse of the silver lining, and has shipped two cars of high-grade ore last week. An important strike has been made in the drift on No. 5 vein at the 80-ft. level of the King Edward, where previously no silver had been found. Ore 11 in. wide and assaying over 3000 oz. per ton, with the wall rock on either side being impregnated with silver, was

found. The McKinley-Darragh has declared a dividend of 5% payable July 15. On the Peterson Lake leasehold of the Little Nipissing a 12-in. vein of calcite with good silver content has been struck on a raise between the 100 and 160-ft. levels. A cross-cut at the 110-ft. level of the O'Brien has tapped a vein found some time ago on the surface. It is 7½ in. wide and will run some 4000 oz. silver per ton. The Silver Lead has sunk a shaft 40 ft. on the north end of its property and will put it down 300 ft. in order to strike the Huronian formation, which underlies the diabase. Forty men are at work trenching. The main shaft of the Hargrave on the Jacobs vein is down 270 ft. When it is down 300 ft. a cross-cut will be run to intersect the vein at that level. Frank Loring, consulting engineer of the Wettlaufer mine, in South Lorrain, reports that \$15,000 worth of ore has been taken out of the shaft in sinking to 60 ft. The statement at the annual meeting of the Chambers-Ferland on June 9 showed cash in hand, \$54,799; ore in transit and at smelters valued at \$21,544; and ore in hand, \$15,257. The active liabilities were \$14,324. A vein of calcite 5 in. wide, carrying native silver, has been found on the Marcel property, James township, and traced 400 ft. Of 19 veins so far found on this location 4 show native silver. A contest for the control of the Peterson Lake Co., which came to a head at the annual meeting at Montreal, May 31, resulted in an amicable arrangement, under which several new directors replaced members of the old board.

The Bartlett mine, Gowganda, has made its first shipment, consisting of 3000 lb. of high-grade ore, by canoe to Latchford. It will assay over 5000 oz. silver per ton. The consignment is made to test the suitability of this route for ore, but owing to the expense it will only be possible, in any event, to send high-grade ore. Vein No. 1 at the Bartlett is reported to be found wider as followed. Other mines at Gowganda have ore sacked ready for shipment as soon as that can be advantageously arranged.

BUTTE, MONTANA.

Amalgamated Report.—British Butte Dredges.—Keating Gold.

The annual statement of the mines of the Amalgamated Copper Co., showing the amount of ore mined, the cost of operating, and the net proceeds for the year ending June 1, 1909, have been filed in the office of the assessor of Silver Bow county for taxation purposes. The reports are of the Anaconda, Boston & Montana, Parrot, Trenton, Washoe, Butte & Boston, Butte Coalition, and the North Butte companies' properties. The total net earnings show an increase of more than \$2,000,000 over those of last year, when the aggregate was \$4,648,254. The figure this year is \$6,719,799. The increase is shown in the earnings of the Anaconda, the North Butte, the Butte Coalition, Butte & Boston, and Trenton companies. The Parrot company not only shows a decrease, but its total costs exceed its gross proceeds by \$12,220. This is due to development that has been under way, and to the further fact that much of the ore mined has been of a low grade. The decrease in the earnings of the Boston & Montana company from the figures of last year is due in part to the enforced idleness of the smelters at Great Falls a year ago, resulting from wash-outs on the Great Northern railroad. Last winter the extreme cold weather also interfered with the operation of the smelters and necessitated a curtailment. The greatest increase is by the Anaconda company, the net earnings of which exceed those of last year by nearly \$950,000. The greatest comparative increase over former years is in the North Butte and Coalition properties, the figures at the former being more than \$700,000, and at the latter nearly \$400,000.

M. H. DeHora, president and general manager of the British-Butte Mining Co., operating a dredge on placer ground west of this city, has gone to San Francisco to arrange for the construction of five more dredges which will be installed as soon as possible, and at an expense, it is stated, of nearly one-half million dollars. Mr. DeHora but recently returned from London, England. He and the London capitalists interested with him have purchased the holdings of Dr. Eisenberg and J. W. Murphy, and now control

fully nineteen-twentieths of a total of 5,000,000 shares outstanding. The company has recently acquired a water-right from Oro Fino gulch, and another large dam is to be built to make room for the operation of the additional dredges. The company has acreage enough to accommodate a score of dredges, and it has been stated that in course of time still more would be set to work. No figures of the clean-up have been given to the public. Mr. DeHora, however, declares that the returns have been eminently satisfactory, larger, in fact, than he had anticipated they would be. It is estimated that the bedrock on the ground being worked is from 2500 to 3000 ft. deep. This will be settled definitely within a short time, for a diamond-drill is to be placed in operation for purposes of exploration along that line.

The Keating Gold Mining Co., operating at Radersburg, in Broadwater county, this State, held its recent annual meeting in Butte, and the reports submitted were of a most satisfactory character. The value of the ore shipped to the Butte Reduction Works since the first of the year amounted to \$166,178.96 gross. The company is now working 85 men. A new shaft-house is being erected and machinery which has cost \$32,000 is on the ground and will be installed. The shaft is now down 400 ft. and will be driven another 100. The directors elected at the annual meeting are: Julius H. Barnes, of Duluth; R. B. Dear, of Superior, Wis.; C. W. Newton, superintendent of the Butte & Ballaklava property here; and James A. McKee and Jesse B. Roote, of Butte. Mr. Roote was elected president and general manager, and Mr. McKee secretary.

Another company, the Ohio-Keating Gold Mining Co., has been formed to operate the old Ohio mine at Radersburg. They have taken a lease and bond on the property and the first payments have been made. George M. Bourquin and John N. Kirk, of this city, have been active in the formation of the company, and with them are interested B. Binnard and H. H. Thomas, of New York; John F. Cowan, of Salt Lake City; and R. M. Calkins and W. H. Penfield, of Butte. Mr. Cowan will devote a portion of his time to the general management of the property. The deepest shaft on the Ohio is down 132 ft., and when work was abandoned years ago because of a flow of water, was in about seven feet of \$32 rock. The ores are sulphides, carrying a large excess of iron over silica.

LOS ANGELES.

Oil Production.—Drilling in Sherman Fields.—Mexican Oil.—Public Lands in McKittrick-Sunset District.

In May \$423,470 was paid in dividends on oil stocks in California. The total amount in dividends paid to date is \$23,450,604. The surplus storage of the 'independents' of Kern river, Coalinga, and the West Side has accumulated rapidly during the last month, and it is stated that 328,000 bbl. have been produced over deliveries to the Associated. Since the decision to build the pipe-line was reached there has been no effort to curtail production. In the Los Angeles district interest is now divided between the wells in the western extension of the Sherman field, 10 miles west of the centre of Los Angeles, and the four wells now drilling in the Raphetto hills, between East Los Angeles and the Whittier field. Concerning the former there are two theories, each advocated by men who are backing their ideas by drilling. One is that the oil formations trend westward from the old Salt Lake field along the southern edge of the Santa Monica mountain, dipping southward at a fairly regular angle and passing below the reach of the drill in the region of the track of the Santa Monica branch of the Southern Pacific railroad; the other is that there is a south-westward extension of the Salt Lake flexure or faulted anticline, toward Plaza del Rey, which brings the oil sand to within 2000 ft. or so of the surface on the hills north of Palms. At the present rate of drilling one or the other of these theories will be proved within the next two or three weeks. Drilling in the Raphetto hills has produced nothing as yet, although the holes are going down fairly rapidly. Most of the wells are located with the intention of tapping

the lower part of the Fernando formation (upper Miocene, lower Pliocene), the same horizon that is productive in the proved territory in the Los Angeles and Whittier fields. Owing to the steep dip of the strata in this prospective field, it is almost certain that the oil-belt, if developed, will be narrow.

There is much interest locally in the statement issued at Washington regarding the Mexican oilfields. According to C. W. Hayes, Chief Geologist of the U. S. Geological Survey, while these fields promise to yield a large quantity of crude oil, its quality is such that it cannot compete under present conditions in the markets of the United States or Europe with the higher grade petroleum of the Appalachian, Illinois, or mid-continent fields. Further, the conditions are such that the demand for fuel oil and refined products in Mexico exceeds the supply available at present or in sight in the near future. There is practically no coal in Mexico, and the railroads now dependent chiefly on Texas, Oklahoma, and English coal could consume several times the present production of oil if it were generally adopted as fuel. The increased production in the Mexican fields therefore will affect the United States by reducing the demand for coal, by reducing the demand for high-grade crude oil for refining to supply the local market, and to some extent by competing in the European market with American refined products. Finally, the conditions in the Mexican fields are not favorable for the small operator, and it is highly probable that production as well as refining will remain in the control of a very few strong companies. The geological conditions under which the oil occurs are such as to increase the hazards and uncertainties encountered in the development of an oilfield, and it is probable that both the difficulty of securing a steady supply of oil and the average cost of production will be correspondingly increased. This statement will undoubtedly have an influence on tariff legislation. It is understood that the Senate will put oil on the free list.

Approximately 444,890 acres of land in the McKittrick-Sunset district have been restored to entry by R. A. Ballinger, Secretary of the Interior. The lands were withdrawn pending an investigation and classification as to whether they were mineral or non-mineral lands.

WASHINGTON.

Geological Survey and Private Information.

The Senate recently asked for explicit information, supposed to have been gathered by C. W. Hayes, chief geologist of the U. S. Geological Survey, regarding the Mexican oil-fields. This information was refused by R. A. Ballinger, Secretary of the Interior, a refusal which was endorsed by President Taft. In transmitting instead a general statement, Mr. Ballinger made an interesting announcement as to the policy of the Survey in regard to private information possessed by its officers. He said: "The confidential relation between the public officials and private individuals has held since the organization of the Survey, and has become essential to its successful work, both in the geologic studies of mining districts and in the collection of mineral statistics. Well logs, mine maps, statements of amount, value, and disposition of mineral products are freely given to the Survey, upon the assurance that they will be used only in drawing general conclusions. These details, indeed, have no general interest of value to the public, except as they are incorporated in general statements of conclusions, although they might be used by competitors, to the serious detriment of the persons furnishing them. At the present time the mines in every mining district of the country are open to the general geologist, without the aid of any

East and Proprietor, this relation depends the ad-

The working costs of the Robinson operator betrayed, remain the lowest on the field, at \$3 per service would be velopment. Cyanide managers have good

GOLDFIELD, NEVADA.

Clermont Shaft.—Engineers.—Atlanta. — Diamondfield Black Butte.

The management of the Goldfield Consolidated Mines Co. announces that development will be carried on from the deeper levels of the new Clermont shaft on the Jumbo. As the company has heretofore made no attempt to explore its ground below 600 ft. the results are awaited with keen interest. Owing to the angle at which the principal veins dip it was found inadvisable to sink deeper on the Mohawk. At 600-ft. depth much of the ore is at great distance from the Mohawk shaft, and from that level down may be developed and extracted to better advantage from the Clermont shaft. The stopes on the Lucky Boy claim are opening up a large tonnage of top-grade mill ore, and between this orebody and the Red Top shaft a large and even production is being made, the ore averaging \$50 per ton.

A new and important development on the Florence is reported by the management. In the Engineers' vein a shoot of high-grade ore has been cut at the fourth or 200-ft. level, where there is direct connection with the company shaft. The ore is as rich as any found in the mine and is full of gold, much of it yellow and unlike the characteristic bronze gold of the Florence high-grade.

A notable revival of interest in the Atlanta has been brought about by the discovery of a vein carrying a high percentage of gray copper. At a depth of 425 ft. in the Precious Metals Co.'s lease the vein was entered at the end of a 160-ft. cross-cut. It was passed through and the parallel vein opened for a width of 7 ft. The gray copper was in evidence everywhere. First assays showed but \$2 gold, but later tests show \$8. The ore occurs in dacite. Driving is in progress on the vein and sinking will be resumed.

Operations on the Yellow Tiger have ceased, but it is announced that within 30 days sinking from the 700-ft. level will be resumed and the shaft sunk to 1000 or 1200 ft. The work has been performed by the Elks Consolidated lease, backed by John F. Campion and associates. Local reports which have been widely copied in the press have credited the Yellow Tiger with discoveries of high-grade ore, but the best that has been exposed has been a large vein with only nominal amounts of gold. The chief interest attaching to operations at this point is the distance from the producing centre of the camp and the broad scope of work carried on by the company. Leases on the Blue Bell are following narrow stringers of rich ore from the surface, having abandoned work at over 400-ft. depth because of the expense. On the Commonwealth a tunnel is being driven to the vein by lessees operating on the original company workings. The Nevada Gold Ore Mines Co.'s lease on the Gold Bar claim of the C. O. D. Consolidated has suspended operations for the time being, after sinking 600 ft. and starting drifts on a vein of excellent appearance. The principal lease shaft on the Lone Star will be sunk deeper to cut the vein, in which good ore was found at 250 ft. Several shafts are being sunk in the neighborhood of Vindicator mountain, and there is a decided revival throughout the district in point of development on outside territory.

On the claims of the Goldfield Merger Mines Co. development is in progress at the 600-ft. level from the company shaft, and laterals will be opened above this level to explore the known veins which have produced rich ore from the upper levels. Several leases on this ground are producing rich ore from nearer the surface. The Original Velvet lease resumed lately and shipped pay-ore from the start. The Codd lease on the St. Ives has been taking enough ore from a small vein near the 50-ft. level to pay operating expenses; the Kansas City Velvet has shipped quantities of rich ore and its rich vein has widened in the workings lately, insuring a profitable output; and the Combined Mining & Leasing Co. has let a contract for additional cross-cutting to reach the junction of the St. Ives vein and another strong lead from which high-grade ore has been taken near the surface. A complete hoisting plant has been installed on the Nancy Donaldson mine, in the eastern part of the district, and J. C. McCormack will develop this group on a liberal scale. Exceedingly rich ore has been found near the point at which the shaft is being sunk.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Russian lineal measure is as follows: 1 tothka equals 0.01 inch; 1 liniia, 0.1 in.; 1 vershok, 1.75 in.; 1 archine, 2 ft. 4 in.; 1 sagene, 7 ft.; 1 verst, 0.66287 mile. Measures of area are 1 square sagene, 49 sq. ft.; 1 dessiatina, 2.6997245 acres; 1 square verst, 0.43940829 square mile.

Sill is the name given by geologists to a uniform intrusion of molten material between the bedding planes of stratified rocks. They may generally be distinguished from flows contemporary with the sedimentation by the alteration of adjacent rocks above as well as below, and by stringers or dikelets penetrating the superincumbent strata.

Evaporative power, which is also called the caloric value, of a fuel is the number of pounds of water evaporated at 212° F. by the combustion of 1 lb. of the fuel. To express it in terms of British Thermal Units (B. T. U.), the number of pounds of water evaporated is multiplied by 967, which constant is the latent heat of vaporization of water.

Water for ice-making should be taken from the coolest possible source as a matter of economy in refrigeration. In some places artesian water is taken for this purpose. Such a case is that of the United Ice & Coal Co., at Harrisburg, Pennsylvania, where a cost-reduction of 30% is obtained in that way. Where water is abundant cooling towers may be employed to reduce the temperature before freezing in the machines.

Assessment work on a mining claim consists of \$100 worth per annum. Litigation has been active over the question of what constitutes \$100 worth, such suits usually arising where claim-jumping has been attempted. The surest rule for determination of what amount of work satisfies the requirement is to honestly decide whether you would consider the amount done as worth \$100 if it were part of a campaign of development for which you had to pay in the furtherance of gainful mining operations.

Saltpetre has suffered no diminution in demand as a result of bacterial nitrification of soils. The producers of saltpetre (sodium nitrate) in Chile, declare that the attempts at wholesale nitrification through inoculation of leguminous seeds, especially of peas, has failed completely in Germany and England, and that no pronounced success has been attained in the United States. However this may be, the problem of securing cheap fixed nitrogen is still one of the most important of our day.

Mining concessions in Egypt may be of unlimited size. The grants are in the form of leases, for which the price varies according to the kind of metal. The claims are based upon the feddan as the unit, this being equivalent to 1.038086 acres. In addition a tax

of 10% is levied upon the net profit accruing from operating the concession. In the Sudan the areas are limited to the following maxima: gold and silver 160 acres, other metals 360, oil 640, and coal 1280. Leases must be rectangular in shape, and the length may not be more than four times the breadth.

Paramagnetic substances are those more permeable to magnetism than air, which is taken as the standard and represented by 1; diamagnetics are those less permeable than air. Paramagnetics are attracted by a magnet, diamagnetics are repelled. While chemically pure minerals possess magnetic permeability independently of any iron they may carry, in practice it is almost always the effect of a trace or more of iron, either chemically combined or present as an impurity, that is utilized in magnetic separation. Strongly attracted substances are sometimes called ferro-magnetic.

The Kristiania type of copper deposit was named from those near Kristiania, formed by gaseous emanations along a contact between igneous rocks and sedimentaries. Hence they are 'pneumatolytic' deposits. At the type locality in Norway, such masses are found between syenite and Silurian limestones and slates. The minerals constituting the ore consist of chalcopyrite, magnetite, galena, hematite, sphalerite, and rarely bismuth, and arsenical and antimonial sulphides, with garnet, amphibole, pyroxene, mica, epidote, vesuvianite, scapolite, quartz, calcite, fluorite, and axinite.

Tierra del Fuego, or the Magellan archipelago, is remarkable for its mineral resources. Lignitic coals are abundant in many parts, and the quality is excellent, an approximate average being: moisture, 14.5%; volatile hydrocarbons, 43.05; fixed carbon, 42.15, and ash, 9.9. It was estimated by a recent commission that the ratio of efficiency compared with Welsh anthracite was as 2 to 3. Gold exists abundantly, and immense masses of 'low-grade porphyry' copper deposits exist. The maze of islands, compactly grouped, with deep-water channels everywhere, render facilities for mining extraordinary. Extensive glaciation makes prospecting easy. On the west side of the group the climate is no more severe than that of Sitka, Alaska.

Standard abrasion test for road-metal as adopted by the American Society for Testing Materials requires 30 lb. of coarsely broken stone to be available, and that there shall be placed in the cylinder as nearly as may be, 50 pieces weighing 11 lb. The cylinder is placed at an angle of 30° with the axis of rotation. The cover on the cylinder being tight fitting, the material is thrown from one end of the cylinder to the other, this continuing for 10,000 revolutions at the rate of 30 to 33 per minute. At the end of the test the worn material is the part which is fine enough to pass through a sieve having $\frac{1}{16}$ -in. mesh. The percentage of wear may be used in comparing different materials, or the French coefficient of wear, which is $400 : W$. W is the weight in grams of detritus under $\frac{1}{16}$ in. per kilogram of rock used.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Small Cyanide Plants in Colombia.

The Editor:

Sir—Small cyanide plants could do a splendid business here on rich auriferous silver ores. It is very hard, in this country to raise large capital, but there are many available purchasers for moderate-sized equipment. With a small plant it is possible to go on with development, increasing the business slowly. We would be glad to know of firms which would look into this kind of business. I am connected with a company owning a property which yields ore containing pyrite, mispickel, and galena, assaying on an average 60 oz. silver and 1 oz. gold per ton. This concern would be glad to buy such a small plant.

F. PEREIRA GAMBA.

Pasto, Colombia, May 1.

Occurrence of Gold in Placers.

The Editor:

Sir—I hope your prophecy that “a fresh discussion of this interesting topic will ensue,” may be realized. It is not only a subject of deep and wide interest, but also one of great importance. Moreover, as Mr. Garrison remarks, quoting Posepny, certain features of it at least “cannot be easily explained.” The more reason therefore for combination in the effort. In school days we were taught that all placer gold was produced by erosion; that the gold and rocks were carried, together, to the beach or stream-bed; that there the gold at once began a downward course through the gravel; that this descent was rendered possible by a very slight but constant ‘tremble’, caused by the flow of the water throughout the entire mass of gravel whatever its depth; that the gold continued to descend until stopped by an impervious bed—either a band of clay (false bedrock) or bedrock. That theory has much to commend it, and it readily explains why, when the ‘fill’ is composed of clean sand and gravel, without clay, most of the gold, and particularly the coarse gold, is found on or close to bedrock. But there is one phenomenon that it not only does not explain, but which, on the contrary, seems entirely incompatible with it. I refer to the influence exercised by the nature of the bedrock on the distribution of the gold. Rough bedrock, because the crevices act as riffles, is much more likely to carry gold than a smooth bedrock. Smooth bedrock, pitching up-stream, is likely to be richer than the same kind pitching down. On Eldorado creek in the Yukon were numerous bands of a soft putty-like bedrock with a smooth though uneven surface. It apparently made little difference how this pitched, it was always poor, and frequently barren. These bands were generally narrow, but, in some cases, extended throughout an entire claim (500 feet).

Such bedrock-influence as the above is easily explained by supposing that the stream-bed acted like a miner’s sluice-box, but that would seem to entail the further supposition that the ‘run of gold’ occurred during a certain portion only of the stream’s life-time, and that it invariably ceased when the bed began to accumulate gravel, because how could it act as a sluice-box with 50 or 100 ft. of gravel above bedrock? This latter supposition is, of course, untenable, particularly in view of the frequent occurrence of rich streaks resting on clay-bands high up in the ‘fill’. Mr. Garrison doubts the theory of the descent of gold through a body of gravel, because coarse gold is quite often found high up in the ‘fill’. I would suggest as an explanation that such gold has either been captured before it had time to complete its journey, or, and this is more common, it is found in a stratum sufficiently clayey to arrest or greatly retard its downward progress.

There is another theory, a combination of the two I have mentioned, which, if true, would seem to account satisfactorily for all the ‘vagaries’ of placer-gold occurrence. This theory is to the effect that the entire ‘fill’ of valleys and stream-beds is slowly moving downhill. The point that renders it hard for me to believe this is the existence of the above-mentioned gold-supporting clay-bands. Could such bands, sometimes only a few inches in thickness, and not always of a tenacious nature, maintain their continuity while being transported down stream-beds whose cross-section is constantly varying between wide limits?

W. F. COLLINS.

Battle Mountain, Nevada, May 31.

Co-Operative Topographic Surveys.

The Editor:

Sir—In response to your enquiry, I take pleasure in making a statement of the policy of the Geological Survey in the matter of co-operation between the Federal Survey and State organizations.

The question of meeting the co-operation in topography offered by the States has reached a crisis. Last year \$160,250 was offered by 16 States, and, acting upon the advice of the Secretary of the Interior, I decided to limit co-operation on the part of the Federal Survey to \$100,000, or one third of the appropriation. This involved a reduction of at least 20% of the amounts accepted, save in the case of States offering \$2500 or less.

This year approximately \$250,000 is offered by 22 States for co-operation in topographic surveys. Making a percentage cut is only temporizing with the situation. A definite policy is demanded. Until specific provision is made in the appropriation for co-operative work, two general considerations must govern in planning the distribution of the “topographic surveys in various portions of the United States.” First, the special claims of the public lands States, where the Federal interest in the adequate mapping is paramount by reason of public ownership of land. Second, the progress of the topographic map of the United States as a whole, in which connection it is to be noted that the percentage of area surveyed in the

States offering co-operation is already higher than in non-co-operating States—40 as contrasted with 32%—and this difference is by no means wholly due to the amount of work done under co-operation.

The policy which has been determined upon will fix maxima for co-operative allotments, and grade such allotments on the basis of percentage of area already surveyed. A maximum of \$20,000 will be permissible for co-operative allotments, and that only in States of which less than 35% has been surveyed, this being the percentage for the whole United States. For States with from 35 to 70% of area already surveyed, \$15,000 will be the maximum amount permissible, and for States with over 70% surveyed, \$10,000 will be the maximum. Where the co-operative surveys are on a larger scale than is necessary for the topographic map of the United States, the Federal allotments will be adjusted on a basis other than that stated above. Even under this arrangement it is expected that the co-operative allotments by the Federal Survey this year will aggregate over \$160,000. This increase over the amount allotted last year is rendered possible only by reason of the \$50,000 increase in this year's appropriation. The Federal allotments to meet State co-operation will bear their proportionate share of the necessary expenses in connection with the proper execution of the field and office work, but this share is levied upon the basis of only the Federal half of the co-operative work, although it is obvious that the field work paid for by the State funds necessitates a corresponding increase in most of the administrative expenses.

More Thought About Silver.

The Editor:

Sir—Early in the present year I expressed the opinion in your columns that the price of silver would advance materially before next Christmas. This forecast was made after considering the conditions in force in the countries where it was mainly produced and consumed, together with the market fluctuations for a number of years past. I can see no reason as yet for modifying the views then expressed, but the following item, clipped from your issue of May 22, tempts me to send you a few more thoughts on the subject: "Seigniorage, or profit on coinage of silver by the Government, in 1907, the last year reported, was \$9,095,044. In the last ten years the Government revenue from this source has amounted to \$75,684,972."

The United States product for the year 1907, consisting of 56,514,700 oz. (or about 193 avoirdupois tons of 2000 lb. each), had a value, as a commodity, of \$37,299,700. On this it appears that Uncle Sam made a profit of more than nine millions of dollars by the easy, if not wholly justifiable, process of buying the metal at the market price of, say, 50c. per ounce, coining it into money at the ratio of \$1.29 per ounce, and pocketing the difference. It is safe to say that an equal amount was made by the several European governments in the same way, and probably twice as much by those of Asia that are under English, French, and German control, and

mainly by the British-India Mint operations. So that, altogether, in round numbers, the civilized governments of the world must have realized nearly forty million dollars during 1907 in clean profit out of the silver mining industry, without sticking a pick into the ground, which profit, moreover, was in the nature of a direct tax upon the miner. As the gross commercial value of the world's silver crop for that year was \$127,520,029, it looks as if the producer paid a tax of nearly 30% for the privilege of conducting his business. At that rate he will be 'done up' in short order. In fact, the process is already accomplished, for silver is now almost wholly a by-product, and even the producers of lead, copper, and gold, who used to count a little on the white metal in their ores to help them out, have about given up doing so.

But it does seem rather disreputable for governments to be deriving income in that way, and to be dealing so extensively in what is actually a debased coinage, kept afloat by ignorance among the masses, and confidence (not always justified) among the classes. And is it not a fine wind-up to the theories of the gold-standard people, who carried their point by insisting that the poor man's white dollar must be intrinsically just as good as the rich man's yellow one? Of course it won't do to breathe the subject of bi-metallism again. It is out of vogue, and extremely unfashionable. Yet the business men of the great trading nations have for some time been wondering how it is that they make such slow progress in their commercial conquest of the East, which was to be brought about in short order by the adoption of the single standard. It is worthy of note that every now and then fresh proofs arise to show that the Orientals, instead of acting as they were expected to, have taken many steps toward becoming manufacturers themselves, and are certain to continue moving rapidly in that direction. Why not? Labor has not advanced in price among them to anything like the extent it has with us, nor have the values, in their money, of the raw materials they produce.

As an example of how soon questionable policies, when steadily pursued, seem to become justifiable and proper, witness the following remarks in a recent issue of that eminently respectable paper, the *Springfield Republican*, ament the complaints along our northern border of the considerable amount of American silver coins afloat in Canada. It is estimated that quite two million dollar's worth (face value) are circulating quietly there. The main objectors are the bankers, who are advocating legal steps to effect its exclusion. Says the *Republican*: "This would be no advantage to the Canadian banks of issue, since they put out no notes below the denomination of \$5, but there would be advantage to the Dominion Government, which, at the present difference between the price of silver and the face of the coins, could clear a profit of 50c. on each dollar's worth of fractional coin minted to take the place of the United States coin circulating there." The *Republican* seems to see nothing wrong or discreditable in the procedure suggested, all American coins being afloat on substantially the same footing.

Something might be done for the white metal if the producers got together and made public protest against this debased condition of silver coinage the world over. It would, of course, be impracticable as well as inadvisable to put more metal in the coins. But perhaps the subject is a more vital one at present to Europe than to America. With our immense internal trade, that of Canada and Mexico immediately adjoining us, and the whole of Latin America to the south, we can afford to wait until England, Germany, and France find the situation intolerable, and take steps toward a solution. The single standard idea originated in Europe, which is but a slight producer of either of the money metals, but, for a thousand years past has occupied the position of banker, manufacturer, and distributor for the rest of the world. From it as a centre modern civilization has spread in every direction. It has been in a position to demand payment for its goods and services in the kind of coin it preferred, and it chose gold. Coincidentally, however, in those parts of the globe where the balance of trade was against it (notably Asia) it has paid its obligations in silver, which indeed was the only money the East would for a time accept. But during the last fifty years the United States has been steadily encroaching on its trade. Simultaneously the Asiatic balance to be settled has been growing as the East increased its exports. Again, as Europe advanced in manufacturing, its agricultural industries waned, until at present it is extensively dependent for food upon the newer parts of the world. It has drawn its silver almost entirely from the two Americas for the last 400 years.

A very interesting condition of affairs is arising from this combination of circumstances. Europe is losing its gold, and simultaneously some of its trade. At the same time, as the result of international jealousies, taxes have increased so greatly that the burden of life to the poor is becoming intolerable, and the most energetic and valuable citizens are emigrating. Much of the stored up wealth of the rich is also disappearing. Many natural resources are approaching exhaustion. Europe is visibly approaching bankruptcy. If it is to continue deriving support from the sale of its manufactures, it must be able to draw raw material from other parts of the world at cheap prices. Its ability to do this is waning. It has only gold to pay for what it must have, and the value of commodities in terms of the yellow metal is rising everywhere. The alternative is for European manufacturers to move their plants nearer to the sources of raw material, and to the consumers. This movement is well under way, and the movement is most notably toward those countries where silver money is practically the only kind known, and where it still retains its ancient purchasing power. As this trend of affairs becomes more pronounced, the demand for silver will grow, and its price advance. Nothing is more certain than that it is one of the metals most necessary to civilization, even more so than gold.

Meanwhile silver producers would do well to get together. In this age of the world publicity is one of the most valuable of weapons, both for offence and defense. The general public has little or no informa-

tion as to why the metal is such a drug in the market, and what an outrageous tax the producer of it has to stand. Few bankers or financiers grasp the fundamentals of the subject of money. This is inevitable, for, after all, their work is simply to effect the processes of exchange, regardless of the nature of the materials and tools of the business. But it is the proper task of the producer to stimulate the market for his goods. Until the silver miner takes this work vigorously in hand, the rest of the world will go stumbling along on its wonted way, wondering vaguely, when it does think on the subject at all, what the metal was made for anyway, unacquainted with the wonderful part it has played in the past in the history of commerce and civilization, and unconscious of the rôle it is cast for in the future, when the thousand million Asiatics take their inevitable and rightful position among the nations of the globe.

Mixed Geography.

The Editor:

Sir—For some months I have not been in touch with your journal and have only recently seen your issue of January 23, 1909, and on page 147 I noted with some surprise your clipping commenting on an article by myself and headed 'Mixed Geography'. I enclose a copy of a letter I am sending to the Editor of the *Queensland Government Mining Journal*, and would consider it a favor if you would make a similar correction.

G. M. COLVOCORESSES.

New York, June 3.

[The letter referred to is given below.—EDITOR.]

Sir—I have just seen the enclosed paragraph on 'Mixed Geography' in the MINING AND SCIENTIFIC PRESS of January 23, 1909, which appears as a clipping from your paper and accuses me of saying that "Mt. Morgan is best reached from Queensland, New South Wales, etc." I would suggest that when you quote and criticize articles appearing in other periodicals it is a good plan to have the periodical itself before you and make quite sure that your quotation is correct. In this case no such statements were ever written by me nor did they appear in the *Yale Scientific Monthly*. My article appeared in the issue of April 1908, which is before me as I write and the statements which you so misquoted were as follows: "'Mt. Morgan' is located in the State of Queensland 25 miles inland from the seaport of Rockhampton in Latitude 23° S. * * * To reach 'Mt. Morgan' one leaves Sydney, New South Wales, in the late afternoon, on the north-bound express. * * * Rockhampton, though only 900 miles from Sydney, is almost forty hours distant; one passes through some very fine agricultural and grazing country and through the famous mining camp of Gympie." I trust my geography will meet with your approval and that you will do me the courtesy to publish correctly these quotations from my article and withdraw your previous comments.

G. M. COLVOCORESSES.

HISTORICAL GEOLOGY OF CALIFORNIA.

Written for the MINING AND SCIENTIFIC PRESS
BY WILLIAM FORSTNER.

Literature on the historical geology of California is scattered through a great number of publications, and any engineer requiring data on this subject must search through a long list of works to find the different views expressed on the subject. The data are contained in the detailed descriptions of different portions of the State, which are found scattered through the publications of the U. S. Geological Survey for the Sierra region and northern California and in those of the University of California, the State Mining Bureau, and various technical periodicals. The object of this paper is to collect and epitomize this literature so as to serve as a guide.

Archean.

Evidences of Archean masses, principally gneisses, have been found at some points in the Sierra Nevada

Map of California.

region, and probably in San Bernardino county. These gneissoid rocks have been brought to the surface at many points by upheaval and erosion, and the suggestion that they are of Archean age appears well founded.¹

Paleozoic.

During the Paleozoic era the Archean land mass lying west of longitude $117^{\circ}30'$ probably extended westward, including part of the area now occupied by the Sierra Nevada. Its western shore was apparently somewhat west of the present crest, although it is by no means impossible that an Archean land mass existed on the site of the present Coast range. The

¹17th Annual Report, U. S. Geological Survey, Part I, p. 529; Journal of Geology, Vol. III, p. 387; and Tenth Census U. S., Vol. XIII, p. 47.

Paleozoic sediments, which now constitute a large portion of the centre of the Sierra Nevada range, were laid down in the sea extending westward.¹

The Sierra Region. Lower Cambrian rocks have been ascertained to exist in the eastern portion of Inyo county, in the White mountains, and west of Big Pine.² Silurian and Devonian formations have been found in the northern part of Plumas county; namely the Grizzly and Taylorville formations (Silurian), and the Arlington formation (Devonian).³ Outside of these local exposures, no fossils older than the Carboniferous have as yet been found in the Sierra Nevada. The Paleozoic deposits on the western slope of the Sierra Nevada have been summarized under the name of the Calaveras formation, which, while principally composed of Carboniferous sedimentary and igneous rocks, contains also probably older rocks. In some portions of the Sierra these rocks pass so insensibly into amphibolite schists, derived from ancient tuffs, as to suggest that volcanic activity occurred at this period. The rocks of the Calaveras formation have been strongly altered by later earth movements, so that fossils are only occasionally found in the limestones distributed through it; consequently it is impossible to obtain paleontologic data for the differentiation of its subdivisions.⁴ In older geological works the name of 'Auriferous slates' was used, covering besides the Paleozoic, also the Mesozoic deposits. This name, however, is not used in the later works.⁵ In the northern end of the Sierra Nevada, close to the Lassen Peak region, some Upper Carboniferous strata, the Robinson or Little Grizzly creek beds have been identified, and differentiated from the Calaveras.⁶ In that region in close proximity to each other, are the Silurian, Devonian, Carboniferous, and Upper Carboniferous rocks. This occurrence tends to confirm the suggestion that within the range, among the Calaveras rocks, are included those belonging to the older Paleozoic. That these have not been differentiated is because their more thorough metamorphism has obliterated nearly all paleontological evidence.

Northern California. The oldest known rocks in the Klamath region, west of the Sacramento river, are mica (sericite) schist and hornblende-schist, the Abrams and Salmon-schists. Their age is, as yet, doubtful. They may be Silurian or older, but all that can be stated with certainty is that they are pre-Devonian.⁷ The oldest fossiliferous rocks yet recognized are of Middle Devonian age, namely, the Kennett formation; this is overlaid by a heavy series of eruptive volcanic material, the Copley andesite and Balaklava rhyolite. These are undoubtedly older than the Kennett, but their relation to the crystalline schist cannot be defined, as they are separated from

the schist by a large belt of much younger granodiorite. From these Devonian rocks upward, there is in the Pit River section, a rather complete succession of Paleozoic rocks, intercalated with numerous beds of volcanic material. There are two belts of the crystalline schists running nearly parallel in a north-westerly direction. The southwestern runs from near Ono, Shasta county, through Trinity and Humboldt counties. It forms the South Fork mountains, the divide between Mad river and the South Fork of the Trinity river, and reaches the coast near the mouth of Redwood creek. The other belt runs through the Bully Choop and Salmon mountains, continuing northward into Siskiyou county. Between these two belts lies a belt of highly metamorphosed Devonian and Carboniferous sedimentaries, associated with large masses of various igneous rocks, which latter cover a far larger area than the sedimentaries.⁸ The western schist-belt is limited to the west by Mesozoic rocks, and apparently there is here a fault, which has elevated the block of the Klamath region. All the strata dip to the northeast. To the east of the northeastern belt are extensive masses of rocks of igneous origin, and then comes the wide belt of Paleozoic and younger rocks, crossing the Sacramento river, all dipping eastward. The volcanic rocks underlying the Kennett formation have been laid down on land; subsequently there must have been a subsidence, allowing the deposition of the marine Middle Devonian (Kennett). To the west of Gazelle, Siskiyou county, limestone containing an Upper Devonian fauna has been found; this formation has not been found in Shasta county, and here the Lower Carboniferous (Bragdon) rests apparently on the Middle Devonian. The Lower Carboniferous (Bragdon) consists partly of volcanic material, especially its upper portion, which is sometimes designated as the Baird formation; then comes, in ascending order, the Upper Carboniferous McCloud limestones, overlaid by the McCloud shales or Nosoni formation, chiefly tuffs; and further eastward the Mesozoic rocks. These formations have generally the structure of monoclines with an easterly dip, which leads to the suggestion that in this region the shore-line of the early Paleozoic sea was by a series of uplifts, accompanied by volcanic activity, gradually pushed eastward.⁹ The important copper deposits west of the Sacramento river are situated in the pre-Kennett volcanics; the epoch of their formation is, however, as yet unknown. In Siskiyou county most of the copper deposits are situated in the areas of schist, often in quartzite belts included within these schists. The Paleozoic rocks were in later times intruded by basic rocks, to a great extent altered into serpentine, and subsequently invaded by huge masses of granodiorites.

Coast Ranges. While the age of the basement complex of crystalline rocks—granite, gneiss, crystalline schist, and metamorphic limestone—is not yet positively ascertained, it has been suggested as a hypothesis, that they may be Paleozoic, and it has

been shown that there are some reasons for considering them to be Carboniferous.¹⁰

Southern California. In the range running west from the Tehachapi to the coast occur gneisses and schists, which may be Paleozoic or older.¹¹ The Peninsula range embraces the San Jacinto, San Bernardino, and Santa Ana ranges, and continues southward as one mountain chain, forming in its southern portion the backbone of the peninsula of Lower California. It is formed wholly of crystalline schists and massive rocks, respecting the age of which there is great diversity of opinion.¹² It may be Paleozoic.

Mesozoic.

Sierra Region. The Trias is only represented at the two extremities of the Sierra Nevada. Southwest of Mt. Whitney are the Mineral King beds;¹³ and in the extreme northern end of the Sierra, in the Taylorville region, are the following Trias formations: the Swearinger slates, resting unconformably upon the Carboniferous; the Hosselkus limestone; the Trail beds; and the Foreman beds. They consist principally of slates and limestones. There is an unconformable relation between these Triassic beds and the overlying Jurassic.¹⁴

After the close of the Carboniferous, and before the deposition of, at least, the later Jura-Trias, an upheaval took place by which the Carboniferous and older sediments were raised above sea-level, folded, compressed, and rendered schistose. Smaller masses of granitic and other igneous rocks were probably intruded at this time. Then, after a considerable interval, followed the intrusion of the diorite-gabbro-pyroxenite group, and subsequently that of the diabase and allied porphyrites, or meta-andesite group. The age-relation of these intrusions with the Jurassic Mariposa beds is not clearly determined; they all have been greatly altered by subsequent earth movements, and to a great extent have been rendered schistose. There is reason to suppose that eruptions of the last-named group occurred both in Carboniferous and Jurassic times.¹⁵ Considering the above mentioned distribution of the Triassic rocks, there is a probability that the mass of the Sierra region was above sea-level during that period; that this land mass was bordered on the north by the ocean, along the depression of the Lassen straits, and that a local submergence took place at the north end of the Sierra Nevada. The above noted Trias-Carboniferous unconformity in the Taylorville region, which is not found north in the Pit River region, confirms the hypothesis. The presence of the Jura-Trias unconformity in this region indicates that it was also included in the general pre-Jurassic disturbance which involved the entire region of what is now California. In the main Sierra region are some Jura-Trias beds, the Sailor Canyon, Milton, and Monte de Oro beds, lying unconformably on the Paleozoic.¹⁶ In the Northern Sierra the Lower and Middle Jurassic are

represented by the Hardgrave sandstone, Thompson limestone, and Mormon sandstone.¹⁴ During the earlier part of the intrusions of diabase and porphyrites above recorded, the land area of the western portion of the Sierra Nevada subsided and the late Jurassic Mariposa beds were laid down.¹⁶ After the deposition of the Mariposa beds and the close of the accompanying igneous activity, the important post-Jurassic orogenic disturbance, which also involved all the region west of the Sierra Nevada, took place. As a result of this movement the Sierra Nevada was uplifted as a great mountain range. This movement was accompanied, or followed, by the most far-reaching phase of igneous activity in the form of large batholiths of granodiorite, which took place at a great depth, but now revealed by erosion.^{15 16 17}

The last phase of the history of the 'Bedrock series'

now covers the Sacramento valley, as there are evidences that during the Cretaceous the Sacramento valley was gradually subsiding under the great load of sediment brought into it, both from the Sierra Nevada and from the Coast range, while probably at the same time these two ranges were gently rising.¹⁹ According to another hypothesis, it is doubtful whether during the Cretaceous anything at all comparable with the present Sacramento valley existed, and that the shore-line was west of the present eastern rim of that valley.²⁰ For the subdivision of the Cretaceous, see below, under, 'Coast ranges.'

Northern California. The Klamath mountains and the Cascade range are separated on the south from the Sierra Nevada by a broad depression in the pre-Cretaceous rocks, running transversely to the general trend of the Sierras, and named the Lassen

Sierra Nevada Foothills Near Copperopolis.

(Paleozoic and Mesozoic rocks of the Sierra Nevada) was the formation by compressive stresses of an extensive series of joint-fissures, in different directions, generally, however, not coinciding with the old lines of dynamic disturbances. Along these joints and fissures ascending thermal waters altered the country rock, deposited the ores, and their age is therefore early Cretaceous.¹⁸ Some of the gold-quartz veins of the Mother Lode, however, were formed prior to the deposition of the Mariposa formation.¹⁸

During the Cretaceous the Sierra Nevada range was greatly eroded, and no Cretaceous rocks are found in the Sierra Nevada except on the lower west slopes, in the northern part of the range, and a small isolated exposure north of Lincoln. It is, however, possible that the Cretaceous along the west slope of the Sierra Nevada is overspread by the alluvium that

strait. This depression was beneath the sea-level during Chico times.²¹ The correlation of the pre-Cretaceous formations on Pit river and near the North Fork of Feather river, confirms this hypothesis. The older Mesozoic formations are differentiated from the Cretaceous by their thorough metamorphism. In the Pit River region the Trias is represented by the Pit shales, Swearingen slates, Hosselkus limestone, and Brock shales; the Jura by the Bend formation, which includes at its top the Mormon sandstone, or the Modin and Potem formations.²² In this region the Jura-Trias unconformity is clearly observable. The Triassic and Jurassic volcanic activity, to which are due the Dekka andesite and the Bully Hill rhyolite (Trias), and the Bagley andesite (Jura), was submarine, which indicates that the

Pit River region was not elevated above sea-level during pre-Cretaceous Mesozoic times.

The copper deposits near Copper City and Ingot, formerly Furnaceville, are in the Triassic eruptives, but their age is unknown. After the deposition of the latest known Jurassic sedimentaries (the Potem), and before that of the Cretaceous, this region was involved in the post-Mariposa volcanic activity, already noted in the Sierra region. This occurred chiefly along or close to the western rim of the Triassic, throwing long apophyses into the Carboniferous. These igneous rocks range from granodiorite to hornblendite, and in structure from batholithic to narrow dikes.²³ Their occurrence would indicate that they represent differentiated extrusions of one magma. The granodiorite is very similar to that of the Klamath region.

In the Lassen Strait region the Chico is the only representative of the Cretaceous. It is exposed in the form of long tongues, which have been uncovered by the erosion of the younger formations. During the earlier Cretaceous this region formed part of the land-area of northwestern California and southeastern Oregon. Then followed a period of subsidence, until, in the latter part of the Cretaceous, the ocean reached to the western base of the Sierra Nevada and to the Blue mountains in Oregon. This depression evidently did not include the region north of Pit river, as here no Cretaceous has been found. During the earlier Cretaceous there must have been numerous earth-movements, and the lower portion of the Cretaceous is much more disturbed than the upper, Chico portion.²⁴ The Jura-Trias history of the Klamath Mountain region has yet to be worked out in detail. About the close of the Carboniferous, and before the deposition of the Triassic, there was an extensive movement, resulting in uplifts accompanied by extensive volcanic activity, by which portions of the Klamath mountains were elevated above the sea. Strata of Triassic and Jurassic age may have once covered the Klamath region and have been removed by subsequent erosion,²⁵ but according to the latest data, no Jura-Trias deposits have been found west of the Sacramento river in this region. In the Klamath mountains the post-Jurassic volcanic epoch is represented by huge masses of granodiorite and more basic eruptives, the latter being altered into serpentine over large areas. The granodiorite formed numerous extensive belts, a large one of which forms the Trinity and Scott mountains. Considerable deformation and alteration of the older strata occurred during this period of volcanic activity. The Klamath Mountain section was uplifted to a higher altitude than before.²⁶ While the principal exposures of copper ore are in the Paleozoic or older formations, the gold-quartz veins are mainly in the granodiorite. A genetic similarity with the gold-quartz veins of the Sierra Nevada is to be noted. This epoch of mountain-building closed with the Pacific coast of northern California from 10 to 30 miles west of the present coast line,²⁶ and during the earlier Cretaceous (Knox-

ville) the Klamath region remained above sea-level. The Klamath mountains are surrounded by Cretaceous sediments, and isolated patches of Cretaceous strata occur at a number of points in these mountains.²⁷ Whether the entire Klamath district was submerged in the latter portion of the Cretaceous, or whether a portion formed an island, is as yet a disputed point. During the Knoxville the Klamath mountains were deeply eroded, and the detritus was deposited in the littoral. As the region subsided, parts of the interior became submerged, and the Horsetown, besides overlapping the Knoxville which surrounds the Klamath mountains, covered at least a part of the interior, and its remnants may be found in four detached basins lying on a line about E.N.E. from Rattlesnake creek to Redding creek. Their present condition is due to a post-Cretaceous folding of the strata in that direction, leaving the remnants along the axis of a syncline, with the axis bearing N.E. The direction of this disturbance is almost perpendicular to those which determined the distribution of the Paleozoic formations. We have thus in the Klamath district two main systems of folding, nearly at right angles to each other.²⁸ The Chico surrounds the Klamath region, and remnants are found in several places in the Klamath mountains.²⁹ The Cretaceous represents in the Klamath region and the Coast range a long period of relative absence of volcanic activity, combined with subsidence. At the close of the Cretaceous, orographic movements occurred, the Klamath Mountain region was uplifted above sea-level, and has remained so ever since.³⁰ This uplift was not regional, for both to the north and south Eocene deposits are found in the Coast range.

Coast Range. The historical geologic record of the Coast range begins in the Mesozoic. The crystalline basement complex may be Paleozoic, or may include Paleozoic rocks, but this is mere hypothesis. Between these crystalline rocks and the well defined Lower Cretaceous rocks appears a series of rocks which have variously been called the Metamorphic series, the pre-Cretaceous, the Golden Gate, and the Franciscan. The last name is at present generally adopted. This series consists of a basal conglomerate: a moderately fine-grained, greenish or bluish-gray sandstone, weathering yellowish: limestones, radiolarian cherts, volcanic rocks and lavas, serpentized intrusives, and cherts affected by local metamorphism.³¹ These form an irregular complex. The metamorphism resulted essentially in re-crystallization, serpentization, and silicification;³² and the characteristic structure which serves for its ready identification is due to sudden and sharp disturbances, resulting in crushing and fracturing the strata, rather than to uplifting and

folding.³³ The uniform, characteristic lithological features of this series, which render it easily identified in the field, are very valuable, as there is a scarcity of fossils. The series is certainly younger than the oldest known Californian Cretaceous, the Knoxville. Whether the latter is at the base of the Cretaceous or not is a point of dispute.³⁴ The metamorphism of these beds is probably due to the post-Jurassic disturbance. They are younger than the crystalline basement complex, and separated from them by a long interval of time, but as the age of the latter is also undetermined, all that can be stated with certainty regarding the age of the Franciscan series is that it is pre-Cretaceous Mesozoic.³⁵

There has been discussion as to the character of the radiolarian chert; it has been variously defined as phtanite, jasper, and chert. It consists of thin

Slates of the Sierra Nevada, Placerville, California.

beds of radiolarian cherts with much thinner shale partings. The rhythmically thin bedding of these cherts remains as yet unexplained.³⁶

Throughout the series are a number of volcanic rocks, including basaltic lavas, diabases, and pyroclastic accumulations, which furnish abundant evidence of intermittent volcanic activity during the deposition of the sedimentaries of the Franciscan series. There is here a noteworthy similarity with the Lower Mesozoic in the Pit River region. There, however, the alteration of the rocks was not so great as to destroy all paleontological evidence. The rocks

of the Franciscan series were finally intruded by peridotites and pyroxenites, now largely altered to serpentine, which have caused, by contact metamorphism, the local formation of crystalline schists of a wide range of petrographic character; but principally glaucophane-schists. The age of this intrusion is also a matter of discussion. By some it is claimed to be pre-Knoxville; others claim that portions of the Knoxville have been invaded by these intrusions.³⁷ These often occur at the contact of the Franciscan and the Knoxville. North of the bay of San Francisco the Coast range, or ranges, consist principally of the Franciscan series. South of the bay the ranges near the coast, the Santa Cruz-Gavilan range and the Santa Lucia range, consist mainly of rocks of the crystalline basement complex, but Mount Diablo consists chiefly of the Franciscan series, which sinks beneath the Tertiary near Polonio Pass. The Franciscan series forms the axis of the Cujama range, and its most southerly exposure is on the west slope of the San Rafael mountains.³⁸ They have not been observed in southern California.³⁹

The Cretaceous beds are found throughout the Coast ranges, principally along the eastern slope. They have their greatest development in Tehama and southwestern Shasta county, and must have covered a large part, if not the entire area, of the present great valley (see above, under Sierra region). They were apparently derived from the erosion of both the Sierra Nevada and the Coast ranges. The Cretaceous is split into four divisions, which are, in ascending order: the Knoxville, predominantly dark shales, with thinly bedded sandstones, except in southern San Benito county, where the sandstones predominate; impure limestones are frequently found in this formation; the Horsetown, predominantly olive-colored shales with some thin beds of sandstone, at the base generally a conglomerate (these two form the Lower Cretaceous or Shasta series); the Wallala beds, sandstones and conglomerates, locally developed on the coast of Mendocino and Sonoma counties (they may properly be considered as a phase of the Chico); the Chico, predominantly soft sandstone, with some shale beds.

The overlapping of the younger beds upon the older, clearly indicates the continuous subsidence of the continent during Cretaceous times. There is evidently a faunal continuity between the Knoxville-Horsetown beds and the Chico, although there are marked indications of disturbances during the long period of deposition, the Lower Cretaceous beds being generally much more disturbed than the Chico,⁴⁰ which resulted in local non-conformities.⁴¹ From the distribution of the Cretaceous in the Coast ranges, it is evident that a part of it did not subside beneath sea-level during that period, as, especially in the southern portion, the Lower Miocene is in many

places found resting on the Franciscan. The most southern exposure of Cretaceous strata in the Coast ranges as yet known is found near Point Sal, Santa Barbara county (Knoxville) and in the San Rafael mountains (Upper Cretaceous?).⁴²

Southern California. Our knowledge of the Mesozoic geology of southern California is, as yet, quite limited. Rocks of the Metamorphic series (Franciscan) are mentioned as occurring at several disconnected places, and there are Cretaceous rocks at Point Loma, east of Carizo Springs, and in Silverado canyon, in the Santa Ana mountains. The granitic rocks of the San Gabriel and Santa Monica ranges, micaceous gneisses and granites, are probably of late Jurassic age. Near Newhall they contain a very light oil.⁴³

(To be Continued.)

South Australian Mining in 1908.—A review of mining operations in the State of South Australia for the half-year ended December 31, 1908, is contained in Bulletin No. 9, recently issued by the Mines Department of that State. The total value of all minerals won for 1908 was £457,900, against £814,220 for the year 1907, the decrease amounting to £356,320, or a reduction of over 43%. For the months under notice standard copper averaged £61 ls. per ton, and for the whole year £60 Os. 10d. per ton. The mineral leases numbered 1205, comprising an area of 100,387 acres; the registrations for the last half of 1908 numbering 641, with an area of 44,429 acres. The number of men employed totalled 6350, copper mines employing 4470; gold, 880; salt, 450; silver-lead, 50; other minerals, 500. The returns from the Government crushing and cyaniding plants show that 1216 tons were treated, yielding 1208½ oz., valued at £3887, the average yield per ton being 64s. In the Northern Territory, the Arltunga battery and cyanide plant treated 344¼ tons for 387½ oz., valued at £1401; and at the Winnecke's Depot, 263¾ tons for 114 oz., valued at £427 6s. In regard to subsidies to mining companies, it is shown that since the inception of the system, the total advanced was £46,231 10s. 4d., of which £6055 12s. 6d. has been recovered, leaving a debit balance of £40,175 17s. 10d. A portion of this outstanding debt is represented by machinery that has fallen into the hands of the Government, and, the report says, "add to this the value of the metals won, and the State in general will probably have benefited beyond the money value of the debit balance." In two instances only have the profits won enabled full repayment—the Crystal mine, at Echunga, which repaid £76 7s. 6d., and the once famous New Alma and Victoria mine, Waukaranga, which repaid in full the first subsidy of £3000. The remainder of the recoveries was derived from sales of mining plant.

Saghalien is to become a producer of oil. A German company has secured a concession to operate on the east coast of that island, where good oil has been found in abundance at 120 feet.

KNUDSEN PROCESS OF PYRITIC CONVERTER SMELTING.

Written for the MINING AND SCIENTIFIC PRESS
By O. BERGSTROM.

I had the opportunity of seeing the operation of the Knudsen converter at the smelter of the Sulitjelma Aktie Bolag, at Sulitjelma, Norway. The process was invented by Emil Knudsen, the manager for the Sulitjelma company. It is protected in the United States by patent No. 721,311, of February 24, 1903. It has now been in operation four years, practically without any change except an increase in size of converter charges from 8 to 12 tons. This increase has shown many advantages in the operation of the converter, and there is now a 20-ton converter in course of construction. The ore smelted at Sulitjelma consists mainly of copper-iron pyrite with 15% silica. It is fluxed with an ore containing 60% silica, so that the composition of the charge is as follows:

	Per cent.
Copper	6.31
Sulphur	36.02
Iron	33.25
Alumina	3.41
Silica	21.00

The furnace in which this charge is smelted is a converter with a bottom of peculiar shape. This shape has been found necessary to obtain a bath of fused material quickly. The furnace is lined with magnesite bricks, which lining is usually renewed every 30 days, especially in the smelting zone. In starting the furnace, about 200 lb. of bituminous coal is shoveled into the converter, a gentle blast turned on, and a 12-ton charge of the above composition is introduced.

Through the courtesy of Mr. Knudsen the 12-ton converter was placed at my disposal for a period of 10 days, which time I devoted to proving the process in regard to the silica percentage possible in the slag, and also the concentration that could be obtained in the furnace. The slags thus produced varied from 25 up to 40% SiO₂, without affecting the time of the operation, the slags highest in silica being somewhat lower in copper. The complete settling of the slag at the time on a large scale was not possible, as the reverberatory forehearth was not ready. Settling tests made in large crucibles showed that slags from a 50% matte, which were allowed proper time for settling, contained about 0.5% copper.

The concentration can be carried to any degree desired, regardless of the silica percentage in the slag. The lowest percentage of copper in any charge that I could use at the smelter was 3.55; it was blown up to a 72.39% copper matte in 4 hours, and the slag after 5 minutes settling inside the converter assayed 0.78% copper. The wear and tear of the lining I found to be practically all mechanical, partly caused by grinding and friction of the raw ore charged, partly by the expansion and contraction due to the variations of temperature to which the furnace is subjected. There seems to be no chemical action on the lining, as the slag analysis showed only a trace of magnesia. As the renewal and wear of the magnesite lining is the most expensive part of the process, fire-

⁴²Bull. Dept. of Geol. Univ. of Cal., Vol. 11, No. 1, p. 18; and Bull. No. 322, U. S. G. S., p. 28.
⁴³11th Rep. Cal. Sta. Min. B., pp. 76-129; and Bull. No. 309, U. S. G. S., pp. 5 and 145.

brick may be substituted for the lining in the upper portion of the converter. This will probably last as long, and make a difference in the first cost.

The blast is started with low pressure until a good portion of the charge is molten; it is then slowly increased to 20 lb., and continued until the flame at the nose of the converter indicates that the proper grade of matte has been reached, when the contents of the converter are emptied into a forehearth or settler by tilting. The time necessary for one charge is 3 to 4 hours, so that 5 to 6 charges can be treated in 24 hours. The blowing engine is of German make, with one cylinder, 38 by 38 in., operated by water-power. It delivers about 4000 cu. ft. of air per minute. The labor at the furnace is 1 charge-wheeler and 3 furnace attendants per shift, the total smelting cost being \$1.05 per ton. This cost will be considerably reduced with the 20-ton converter.

From the above it is readily seen that this smelting is strictly pyritic. No fuel is used, with the exception of about 1% of the charge in starting the burning of the pyrites. This fuel may be coal, coke, or wood. After the sulphide has started to burn, the oxidation of the sulphur and iron, with the formation of the silicates, will supply abundant heat to complete the operation. The great fluidity of the slag, even when highly silicious, shows that there is an excess of heat developed. Ores with a sulphur content as low as 24% can be smelted in this furnace.

Later types of the converter are larger, the increase in the size being principally in the length. It is now supported on wheels, on account of its great weight, and not on trunnions, and is tilted by electric power. A new double-cylinder blowing engine is being installed, as it was found that the one previously in use could not supply sufficient air-pressure for all the tuyeres. Several have been plugged, and the charges are 15 tons, instead of 20. Sometimes in the smaller converters the charges used to 'hang up' or stick to the sides; meanwhile the matte in the bath was subject to the blast and became too high in copper before the mass was brought down. This does not occur in the large converter, the charge sinking more uniformly. Concentrate or fine ore may be smelted in quantity up to 30 or 40% of the lump ore without more loss than in the reverberatory.

Hot-blast has also been tried. The effects were the same as in blast-furnaces, namely, open and bright tuyeres. However, it was found to possess no merit. In fact, it was detrimental to the furnace, and therefore discontinued. With regard to the lining, the writer suggested that the bricks be laid on edge instead of flat, in order to strengthen them against destruction from large pieces of ore in charging from a chute. This change, in addition to a modification of the bottom of the converter, and the increased capacity, has resulted in a great saving of the lining

in fact, only one-third of the number of bricks per ton of ore smelted are now used as compared with five years ago. The matte produced contains 45% copper, which is best suited for the small silica-lined converters; the slag has been settled in the fired forehearth, and the copper assays of the slag show about 0.5%. The metal losses are about the same as in the American plants and practice. The matter of costs

demands consideration. These have been lowered considerably on account of the saving of magnesia bricks and the increased capacity. Blister copper can be made by the Knudsen furnace, but not economically, and should not be recommended. The advantages which the process offers over pyritic smelting in blast-furnaces are mainly great simplicity, high concentration, even with high-iron slags, and the practical elimination of all carbonaceous fuel. By utilizing the waste heat from the fired forehearth to generate a part of the power required for the blowing engine, or by using cheap electric or water power, the cost of smelting by this method will in many instances be considerably lower than the cost by other processes now applied to the treatment of sulphide ores, and the Knudsen process deserves therefore the consideration of the progressive metallurgist.

DREDGING IN VICTORIA.

In Victoria the official term 'dredge mining' is applied to bucket dredging, hydraulic sluicing by centrifugal pump and by the jet elevator; while the term 'hydraulic sluicing' is applied to gravitation plants. According to the report of E. H. Goodenough, acting officer in charge of the dredging branch of the Mines Department, there were, on December 31, 1908, 47 bucket dredges, 71 pump sluicing plants, 6 hydraulic sluicing plants, and 5 jet elevators at work. The number of leases held amounted to 239, covering an area of 24,053 acres. During the year 20,703,092 yards of material were treated with a return of 105,808 oz. gold, valued at £422,234, or an average of 2.4 gr. per cu. yd. of solid matter dealt with. The area worked was 777 acres, which averaged 134 oz. per acre. The gold produced shows an increase of 6346 oz. over 1907. The total expenditure in wages paid and maintenance was, approximately, £305,000, while dividends paid amounted to £63,784, an increase of £25,679 on the previous year. Tin produced during the term amounted to 62½ tons. The initial cost of the plants at work was £646,426. Some ingenious methods are used to stack the tailing at high levels. In some cases the gold-saving boxes are placed in the paddocks at race level. All the material sluiced is run through the boxes and the gold saved before the debris reaches the pump-hole. This enables the delivery pipes to be set at a flatter grade and to deliver into one short length of box at the head of the tailing pump, insuring 10 ft. more stacking room under ordinary conditions. A patent gold-saving box has also been used rather extensively, with good results, as high as 15% of gold being saved thereby. In this box a break is made, generally half way down. The discharge is caught in a receiving hopper and thrown back a few feet into the head of a set of boxes placed immediately below. This break has the effect of immediately precipitating any gold, especially fine floating grains, that escape from the upper box. Attempts at re-soiling the dredged ground have not so far been satisfactory. The only system tried has been that of sluicing the soil on the tailing after stripping it separately, and the conditions are not favorable to this in the Ovens River watershed. *Australian Mining and Engineering Review.*

SALT WATER IN STAMP-MILLS.

Written for the MINING AND SCIENTIFIC PRESS

By T. A. RICKARD.

The accompanying photograph illustrates the effect of salt water when used in the stamp-mortars of the Alaska Treadwell mine, in Alaska. During winter when the sources of fresh water are locked by ice, it is necessary to use salt water from Gastineau Channel, an arm of the sea. Even in summer the water from the ditches has a low temperature—about 42°F.—by reason of the chilling effect of the ground-ice. The battery-water is not warmed artificially. An experiment with tepid water was made and it was found that it softened the amalgam too much.

The corrosion of the iron by the sea-water shortens the life of the mortars to an appreciable degree. This is probably due to electrolysis, the salt water

being a salt readily soluble in water, so that it is removed, with corrosion as evidence. At the Exposed Treasure mine, at Mojave, in Kern county, California, it was the practice of Courtenay De Kalb to add common salt (5 lb. per ton of ore) to the ore as it was fed into the chutes above the stamps. This was done in order to facilitate the precipitation of the copper by the battery iron in accordance with the reactions above mentioned; it being found economical to precipitate the copper into the amalgam rather than allow it to become a cyanide in the treatment of tailing. The copper existed as sulphate in decomposing pyrite and went readily into solution.

Some years ago sea-water was in use at a cyanide plant on Cedros island, off the coast of Lower California, and it is stated that no difficulty was encountered from the presence of salt in the solutions. In the Pelatan-Clerici process, and certain other modifications of the cyanide process aiming to precipitate the gold directly from the pulp by

electrolysis, a considerable proportion of common salt was added in order to increase the conductivity of the solution. While these methods have never been widely used, the failures recorded appear to have been due to other causes, and as far as known were not traceable to the use of salt in connection with cyanide.

Another point is the density of sea-water, which has a specific gravity of 1.03 as compared to water at 1. Concentration is affected by the density of the medium employed; other things being equal, the dense medium is the most effective in separating substances of nearly equal specific gravity. Ordinarily an increase in specific gravity of the liquid medium increases efficiency up to a point where the density lies between that of the two solids, a liquid midway in density giving (barring excessively fine particles, that is, slime) an absolutely perfect separation, on the principle of Thoulet's or Sonstadt's 'heavy liquid' sorting of minerals. Taking two solids of

sp. gr. 2.5 and 3, neglecting viscosity of medium, the relative settling rates in water should be:

2.5—1 and 3—1; the ratio of these is $\frac{1.5}{2}$ or 0.75.

With sea-water of sp. gr. 1.03 they would be 2.5—1.03 and 3—1.03. Then $\frac{1.47}{1.97} = 0.7462$ instead of 0.75, so that the difference in this case would be quite small and possibly balanced by the difference in viscosity.

In Western Australia, before the Government water system was completed, the mills used the brackish water pumped from the mine. In some cases this desert water was almost saturated with salts. At Menzies in September 1897, I found that the water used in the Queensland Menzies mill contained 17% salts. For this liquid they were paying \$6.25 per thousand gallons. At Kalgoorlie, the water carried from 10 to 15% of salts, mainly sodium chloride, magnesium chloride and sulphate, calcium sulphate and traces of the carbonate. Sea-water

Mortar Corroded by Sea-Water as Used at Treadwell, Alaska.

acting as electrolyte and the iron of the mortar as the positive element of a couple; the negative element may be amalgam or mercury in contact with the iron, or possibly copper derived from traces of copper sulphate in the partly oxidized pyrite of the ore. Such copper sulphate would be dissolved in the battery-water and then precipitated by replacement of the copper by some of the iron of the mortar—a replacement that would be facilitated by the presence of the chlorides of the sea-water. The couple thus formed would cause the conversion of further amounts of iron into a readily soluble chloride of iron, resulting in corrosion. If the cast-iron itself is not homogeneous, local electrolysis and corrosion may also be started by segregations within it, when an electrolyte such as sea-water is present. Corrosion of a similar character, and due to similar causes, takes place in boilers and tubes in which sea-water is used, and is most apparent in the vicinity of brass fittings. Thus iron chloride is formed, this

contains 3½% salts, mainly common salt. As far as I could learn the brackish character of the water did not injure the screens in the stamp-mills, although it accelerated rust and impeded settling of slime. Although it was more difficult to make the plants look clean than in mills employing fresh water, there were no injurious effects in the battery or the tube-mill, in cyanidation or in precipitation. A. Blomfield, who was shift-boss in the mill of the Lake View Consols, tells me that they had trouble with the settling of slime and the choking of filter-cloths. The amalgamating plates in the pans (used for treating roasted concentrate) kept in excellent order. When a change was finally made from salt mine water to fresh river water, there were many difficulties in the precipitation room. These were soon overcome, in one case (Lancefield) by adding common salt.

In cleaning the tables, in the Alaska Treadwell mill, their surface is first washed with a jet of water to remove particles of ore. A wooden cover is laid over the copper plates, resting on the cleats that fasten the plates to the table: this leaves a 1½-in. space between the cover and plates. All openings along the sides and at the top and bottom are closed with strips of burlap; a hose is inserted at a point one-third the way from the head of the plate and live steam is admitted at a pressure of 35 to 65 lb. The steam is allowed to act for 20 minutes and is then turned off. The wooden cover is removed and the softened amalgam is scraped off with chisels. The amalgam has become as soft as Swiss cheese and about as brittle. The mercury is partly volatilized by the heat, and the men are careful to stand back when the cover is raised. Warning is given by the fact that the brass sockets of the electric lights hanging over the tables become amalgamated. In cleaning the tables, the men wear a wet sponge at their nostrils. When the amalgam has been scraped off, the plate is dressed with a weak cyanide solution: it is then dressed with fresh mercury, using whisk-brooms to spread the globules of mercury uniformly.

In the Ready Bullion mill, at Treadwell, the vanners are provided with wooden rollers, it having been found that the salt water corroded both galvanized iron and steel tubing. This mill uses salt water for eight months out of the twelve.

The ore of the Alaska Treadwell and the adjoining mines is simple and homogeneous. It is unoxidized up to the very outcrop, which was covered with a blue clay that protected the lode from weathering. The gold contents of the ore can be gauged from the assay of the concentrate. When new screens were put in the Seven Hundred mill, the grade of the concentrate fell to \$40, from \$70, per ton. At the same time on the same ore the Mexican mill was making a \$70 concentrate with No. 4 diagonal slot screen, equivalent to about 18 mesh, as against woven wire screens crushing to 30 mesh in the Seven Hundred mill. It is apparent that the concentrate is enriched by fine gold that escapes amalgamation. Re-grinding promotes further extraction, as has been proved by cyanide experiments made by Walter L. Brown. Screen tests show that the stuff retained on 40 mesh

is richest in every case, whether ore-pulp or concentrate. Finer material assays less. In concentrate there is a big decrease below 80 mesh and in ore-pulp below 60 mesh.

The mill last built, namely, the 300 stamps of the Alaska Treadwell, differs from the 240-stamp mill, for example, in having heavier stamps, anvil-blocks, concrete foundations (as against timber foundations), individual cast-iron guides, and direct-connected water-wheels (as against a rope-drive from one single wheel). The vanners are in a separate building. Notwithstanding these improvements, the extraction exhibits but slight difference. The 300 mill shows an average tailing of 19 cents per ton from an ore averaging \$2.31 per ton, while at the 240 mill during the past year the tailing averaged 20 cents from an ore containing \$2.51 in gold. But the new mill crushed 5.5 tons per stamp, while the other crushed 4.51 tons; in consequence the cost of milling is 22 cents per ton in one case and only 12 cents in the other. On the other hand, one pound of iron in the dies crushed 6.28 tons of ore in the 240 mill and 4.88 tons in the 300 mill. These dies were cast in the Treadwell foundry.

Although the Alaska Treadwell is one of the biggest mines in the world, it has no dump. No pile of waste rock has been accumulated in front of the shaft-houses. All the material coming out of the mine passes through the crushers, even the waste, for there is no provision for rejecting such rock as is not milled. Men experienced in mining will be favorably impressed by this fact, as indicating the uniformity of the product coming out of the mine, but the tourist misses the conical waste-heaps usual in mining districts, where a large dump is often accepted as impressive evidence of the size of a mine.

Kapsan copper mines. The most important copper mine in Korea is the well known Kapsan mine, situated in South Ham-Kyung, North Korea, the ownership of which, after a period of four years of negotiating between the Korean, Japanese, and American governments, was, in June 1908, conceded to the American claimants. According to the report of an English engineer who examined the mine two years ago, and confirmed by subsequent examinations by other engineers about nine months later, this mine has been worked for many years and was then producing about 300,000 pounds of smelted copper annually. Analyses of this copper showed it to contain 98% copper and unimportant amounts of gold and silver, and practically no harmful impurities, the balance being chiefly iron and sulphur. The ore occurs as large irregular deposits in limestone, and the mine has, thus far, been worked by primitive native methods. The American concessionaires have now sent engineers to prepare detailed plans for the future operation of this property in accordance with modern methods.

The Japanese mineral output felt the effect of hard times last year. Minerals to the value of 14,000,000 yen were won from the different mines of the country, a falling off from the previous year of over 3,500,000 yen.

PHOSPHATE CLAIMS ON PUBLIC LANDS.

The hearings of the Committee on Public Lands at the last session of Congress on the subject of the disposal of the phosphate lands in Wyoming, Idaho, Utah, New Mexico, and Arizona have just come from the Government Printing Office, and form a most interesting chapter in the history of mining. It will be remembered that after a meeting of the National Conservation Commission last year, in which the statement was made that there was a great scarcity of phosphate in the United States, James R. Garfield, then Secretary of the Interior, withdrew the phosphate lands from entry, pending an investigation into their extent and value. The lands remain withdrawn, the bill introduced by Frank W. Mondell of Wyoming which provided for their location and entry under the placer mining law having failed to pass. Mr. Mondell's bill was intended to clear up a muddled situation. Some of the claims have been entered as placers and others as lodes. In addition to providing that all claims in the future should be entered under the placer mining law, the bill provided that all lands containing phosphate deposits that had heretofore been located under the laws providing for the entry of mineral lode-claims might be patented under the provisions of this law, but that no title so acquired to lands containing such deposits should give the locator any rights beyond the perpendicular limits of his claim. A further provision of the bill was to the effect that in case of conflict between locators under the placer laws and the mineral lode laws on locations heretofore made, the respective claims were to be determined as though the location of these lands under either of the above laws was valid at the time the locations were made.

The hearings on the bill drew out the widest possible divergence of opinion among attorneys representing the owners of deposits, members of Congress, and geologists. It was contended most vigorously that the phosphate deposits were not placer deposits, and should be entered under the mineral lode law. This was denied just as vigorously. It was declared that not only was the phosphate supply of the United States extremely limited, but that there was also a scarcity of phosphate throughout the world. This statement was also combatted with much spirit, the attorneys representing the owners of the deposits disagreeing with the officials of the United States Geological Survey as to the supply available. Those who took part in the discussion were James R. Garfield, Secretary of the Interior; Frank Pierce, Assistant Secretary; George Otis Smith, Director of the Geological Survey; Frank Mondell, Representative from Wyoming; L. E. Payson, former member of Congress, representing locators under the lode land law; Aldis B. Browne, attorney, of Washington, representing the San Francisco Chemical Co., which owns phosphate deposits entered under the placer mining laws; Benjamin Micon, an attorney in Washington, representing Lucius T. Brown, of Nashville, Tenn., the owner of 23 claims in Idaho, located under both the placer and lode laws; and F. B. Weeks, of Washington, formerly connected with the Geological Survey, who had ex-

amined the deposits. Mr. Garfield stated to the committee his reasons for the withdrawal of the phosphate lands, declaring that the Geological Survey officials, in their study of the phosphate question, had called attention to the fact that in a great many localities throughout the country, especially in the agricultural areas of the older States, there had been a rapid loss in the productive value of the soil because of a lack of re-fertilization, and that there would be need in this country for great amounts of phosphate. Mr. Garfield was followed by Mr. Smith, who said that the investigations of the Department of Agriculture had shown that the soil of the country now under cultivation was being exhausted of its content of phosphoric acid at the rate of about 2,000,000 tons per year, and that to replenish it would require at least 6,000,000 tons of phosphate rock annually. "We know that through a period of years the production of phosphate rock has quite rapidly increased in this country," said the Director. "We know that in South Carolina, Florida, and Tennessee the production is now something in excess of 2,000,000 tons per year. We know that the total production has been about 30,000,000 tons, and that since 1900, 14,000,000 tons have been exported to replenish the worn-out lands of continental Europe. In South Carolina, at the present rate of production, the supply will be exhausted in 12 years, and the same in Florida. At the present rate of production it would last over half a century in Tennessee but for the fact that as soon as Florida and South Carolina leave the market the Tennessee production must increase very rapidly, and that means that probably in about 25 years we will see the end of the high-grade phosphate rock in Tennessee. That is what has turned our eyes westward, and there we have supplies much greater than those in the East. While the demand has not been such as to draw upon those supplies, we know that the time will come when they will be in demand. The phosphate areas of the West cover about 7500 square miles; that is the aggregate of the areas withdrawn. With regard to the need of the use of artificial fertilizers, there is no question among the agricultural authorities of this land. They agree that we have been gradually defaulting on our farms, and not only are we already in default, but we are adding to the deficit something like the equivalent of 5,000,000 tons of phosphate rock annually—more than is now produced in the whole world. There is a gradually increasing export of phosphate rock from this country, and there is promise of a greater increase. The Franco-German company is buying Tennessee phosphate land. They have a large paid-in capital, which is mainly held by French and Belgian interests, and they have already bought—I give this on the authority of a trade journal—16,000 acres in Tennessee, and are buying options on 10,000 more. That means that Tennessee phosphate is to go abroad, where they need it."

Frank Pierce, Assistant Secretary of the Department of the Interior, told the committee the condition of the claims that had been already patented in the Land Office, and then made the suggestion that Congress should pass some act which would keep the

phosphates within this country. He declared that this would best be accomplished by leasing the phosphate deposits, providing in the leases that there should be no exports of the phosphates, and also providing against monopoly. Mr. Pierce submitted to the committee a bill embodying this idea. In reference to the claims that had already been located, Mr. Pierce said that if these claims were originally located as placer claims, and were free from fraud, the Department was willing to issue patents; also, if the claims were originally located as lode claims, the Department was willing to issue patents to those locators for lode claims. He further suggested that each bona fide locator have the claims to his land as he located it sent to the courts for the ultimate determination as to whether it be lode or placer. If it be held 'lode', the placer applicant could not take it, unless he had claimed it as lode within a placer; if it be held 'placer', the applicant certainly will take it under a placer location or under a lode location (but without dip rights). Mr. Pierce referred to that clause of the bill which provided that no title to lands under the mineral lode laws shall give the locator any right beyond the perpendicular limits of his claim, and asked that it be stricken out. He said the bill treated of future locations, and classified them as placers, and that the general law provided that placer locations shall not have any extra-lateral rights. He said that if this was intended to refer to locations already made, he did not think that Congress ought to assume to take away the extra-lateral rights of a locator which are granted to him by the general mining law. He suggested that if the withdrawal of the lands was revoked, the lands be treated as though containing placer deposits.

L. E. Payson, representing the locators under the lode law, declared that a lode location was the only proper one. At this point Mr. Mondell suggested that, owing to the nature of the deposits, if a claim was patented under the lode laws, a locator, instead of getting 15 acres, might be getting 15,000 acres. Mr. Smith, of the Survey, made the statement that in Wyoming, near Nugget, the phosphate beds lie in such a way that the extra-lateral right would extend, possibly six or eight miles, up to a point where a fault cuts off the bed. Mr. Payson replied that the man who discovers the lode, puts his money into it, and commences to dig, ought to have the right to follow his dip, just as long as that vein is continuous, no matter if it goes down to the centre of the earth, if the heat would permit him to mine it. In answer to a question, Mr. Payson denied any knowledge of a fertilizer trust. He denied the power of Congress to amend the lode laws in such a manner as to cut off the extra-lateral rights, as this was a vested right. Mr. Pierce coincided in this by declaring that it would be an exceedingly unwise policy for Congress to pass any law that takes away any rights which the mining locator thinks, and has thought for over forty years, are vested rights. Mr. Payson ventured the statement that the proposition to prohibit the exportation of phosphate would have to meet a serious constitutional objection. The Constitution of the United States provides that there shall be no export

tax or duty imposed on the exportation of the production of any State in the Union. In the Constitutional Convention there was an absolute unanimity of opinion that there ought not to be any interference with exportation from the United States of the products of any of the different States of the Union. While the provision was against the imposition of an import tax, he said that that was less objectionable than an absolute prohibition of exportation would be. If Congress has no power to impose an export duty on the products of any of the States, it clearly would not have the power to prohibit the exportation of such productions. The statement was made by Mr. Payson that the supply of phosphate outside the United States was absolutely illimitable and inexhaustible. Mr. Smith took issue with him on this point.

A. B. Browne, of Washington, D. C., representing the San Francisco Chemical Co., told of the claims held by his company under the placer mining law. He made a plea for the recognition of the first locator, whether of lode or placer, following the uniform rule and spirit of the mining law and industry, namely, to recognize the first in time as the first in right. He said that attempts had been made to jump the locations of the Chemical company by eleventh-hour men with lode locations, and suggested that for the future there should be such legislation as would eliminate the extra-lateral right. He asked that the future method of taking these phosphate deposits should be under the placer mining law. Mr. Browne quoted from a letter received from his clients to the effect that the several thousand tons of phosphate which had been sent abroad had been exported at a loss, and that exportation of this phosphate is not profitable after paying transportation charges of the rock for a thousand miles to the Pacific Coast in competition with the South Sea Islands in the Pacific. In conclusion, he said he was not present to antagonize the leasing system, but merely to urge that his people should be protected.

Benjamin Micon, of Washington, representing L. T. Brown, of Nashville, Tenn., who owns claims in Idaho, told the committee that Mr. Brown had entered his claims both as lode and placer, in order to protect them from claim-jumpers. He also asked that all locators, whether under the lode or placer laws, be protected. He declared that there were no vested rights in a mining claim until the claim is patented—in other words, there is no contract at all—and there is no constitutional restriction on Congress against passing a law changing the contract until after a patent is issued and title from the United States acquired.

The last one to appear before the committee was F. B. Weeks, of Washington, formerly of the United States Geological Survey, who declared that the largest phosphate fields in the world were in northern Africa, and that these fields will furnish phosphate to the world for many years—many centuries, probably. Mr. Weeks told the committee that phosphate mining in the West does not pay at present. "There is no question but that if a reasonable rate could be obtained to haul that material from the field

to San Francisco," said he, "and there make it into fertilizer, so that it could be shipped to Japan and Australia, there would be a profit. At the present rate there is nothing in it for anybody. If they build up an industry, it must be done by exporting it to Eastern countries for the next few years, or for a considerable number of years." A member of the committee asked Mr. Weeks if there was any danger of these mines being exhausted in the near future, providing the owners are permitted to operate them and export the phosphate. His reply was, "I cannot see any danger of it."

Since these hearings no action has been taken. The lands are still withdrawn, and a determined effort will be made to get remedial legislation from Congress next winter.

WIND RIVER PLACERS.

Written for the MINING AND SCIENTIFIC PRESS
By J. H. HASTINGS.

During the last few years numerous placer claims have been located on the Wind river, in Fremont county, Wyoming. This river rises in the Wind River mountains, and flows in a southeasterly direction for a hundred miles or more, then makes a big bend, and takes a due north course through the canyon which separates the Owl Creek and Copper mountains, into the Big Horn basin, there taking the name of the Big Horn river. Farther north it enters the Yellowstone river, in Montana.

The value and extent of the river gravel has not been determined by a series of thorough drill-tests, yet enough of such work has been done to indicate a dredgeable quantity of gravel in the bars and flats, with gold from 5c. to \$1 per cubic yard. Several surface tests yielded results as high as \$4.20 per cubic yard, but on account of barren strata the average to bedrock is reduced considerably. The depth to bedrock is about 16 ft., the same being either coarse sandstone or shale. These two sedimentaries occur in alternate layers in the Bridger formation, constituting the greater part of the plains in this district. The gold is very fine, except at the heads of some bars; one nugget was found weighing 0.003 oz. The colors, however, are not flaky, but exceedingly solid and pellety. The gravel consists of about 40% of stones never heavier than 30 lb., and the black sand makes 1% of the total. The following table of measurements was used in estimations made:

1 shovel equals	10 lb.
2 shovels	" 1 pan.
300 "	" 1 cu. yd.
150 pans	" 1 cu. yd.
1 cu. yd.	" 3000 lb.

The weight of gravel per cubic yard was actually nearer 2700 lb., while the average shovelful falls short of 10 lb. On the other hand, a panful of gravel weighs 23 lb. However, the large quantities used for the tests ($\frac{1}{6}$ to $\frac{1}{3}$ cu. yd.) eliminate any possibility of great error. A Keystone drill will be used for the final tests, and the exact volume of the core can easily be calculated.

In making the laboratory tests of samples from a Keystone drill I found it expedient to part the mercury from the gold with concentrated nitric acid,

which was more satisfactory than using a retort, as the small amount of gold obtained from $\frac{1}{6}$ cu. yd. was apt to be squeezed through the chamois with the mercury, and if by luck some was saved from this fate it was sure to stick to the bottom of the retort. The latter was placed in the small gasoline assay furnace, where it was impossible to keep down the temperature. Perhaps with more suitable equipment the retort method would prove efficient.

About 6000 acres of the gravel is now under option to capitalists. The workable gravel extends for 30 or 40 miles, from Boysen canyon to the Bend. The river is from 4 to 6 ft. deep and 75 ft. wide. The fall for the upper 20 miles is about 17 ft. to the mile, and gradually decreases to 7, increasing again to 32 while passing through the canyon. Ten months' operation for a dredge could be depended on, as the channel is only frozen over during December and January. A 60-ft. dam is being constructed at the mouth of the canyon, and it is the intention to erect a power plant during the year. This would furnish power for operation on the river. As the W. & N. W. railroad follows the river after reaching Shoshoni, there would be little difficulty in the transportation and installation of dredges. The Wind river placers afford good opportunity for further development of the dredging industry in this country.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

C. T. H., Goldfield, Nevada: Olivine basalt.

W. A. K., Prescott, Arizona: Actinolite schist.

E. F. J., Canon City, Colorado: Specular hematite.

A. F., Daggett, California: An aggregate of kaolin and tale.

J. M., Knob, California: A contact schist reddened by hematite.

F. T. W., Park City, Utah: Fine-grained hornblende schist.

C. H. F., Randsburg, California: Siliceous dolomitic limestone.

R. E. H., McGill, Nevada: Specular hematite, epidote, and calcite.

J. M. N., San Francisco, California: Pyrite and chalcopyrite in a chloritic talcose schist.

L. N. W., Nevada City, California: No. 1, greatly weathered mica schist; No. 2, serpentine; No. 3, serpentine.

C. C. W., Cannonville, Utah: A sulphur-yellow to greenish substance which yielded a faint but distinct test for arsenic, a test for calcium, and a test for a third substance which was possibly chromium, possibly uranium. Aluminum also was suspected. The material was so extremely scanty and so difficult to separate cleanly from its matrix that no complete nor definite determination was possible.

Copper Production in 1908.

The production of copper in the United States in 1908 was 942,570,721 lb., according to a statement prepared by B. S. Butler which has just been given out by the United States Geological Survey. This is the largest production ever made, exceeding that of 1906 by 24,765,039, and that of 1907 by 73,574,230 lb., or 8.4%. In the following table the production for 1907 and 1908 is apportioned to the States in which the copper was mined. The total is made up of the fine copper content of blister produced and of the smelter output of ingot and anode copper from Michigan.

	1907.	1908.
Alaska	7,034,763	4,438,836
Arizona	256,778,437	289,523,267
California	33,696,602	39,643,835
Colorado	13,998,496	13,943,878
Idaho	9,707,299	7,256,086
Maine		7,027
Massachusetts		7,863
Michigan	219,131,503	222,289,584
Montana	224,263,789	252,503,651
Nevada	1,998,164	12,241,372
New Hampshire		128,112
New Mexico	10,140,140	4,991,351
North Carolina	544,040	14,342
Oregon	518,694	271,191
Tennessee	19,475,119	19,710,103
Utah	66,418,370	71,370,370
Vermont	696,102	
Virginia	57,008	25,087
Washington	122,263	162,201
Wyoming	3,026,004	2,416,197
Maryland, Alabama, and Georgia ¹	90,655	45,537
South Carolina, ² Texas, ² }		
South Dakota ² }		
Missouri and unapportioned	1,299,043	1,580,831
	868,996,491	² 942,570,721

¹Georgia did not produce in 1908. ²Not reported in 1907. ³A portion of this total was reported by one company as electrolytic instead of blister copper. To compensate for the loss in refining there is added pro rata to the States concerned the approximate copper content of the bluestone recovered in the production of the electrolytic copper.

The following stocks were on hand at the beginning and end of the year:

January 1, 1908	125,745,796
January 1, 1909	121,876,759

Stocks decreased during 1908.. 3,869,037

Undelivered sales are excluded from these figures. Stocks carried by consumers and brokers have not been ascertained. In addition to the stocks of refined copper there were at smelters, in transit to the refineries, and at the refineries, blister copper and material in process of refining to the amount of 175,254,659 lb. January 1, 1908, and 234,013,843 lb. January 1, 1909. The apparent consumption of refined new copper in the United States in 1908 was about 480,000,000 lb. In addition, probably 23,000,000 lb. derived from secondary sources entered into the year's consumption.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

ELECTRO-MAGNETIC ORE SEPARATION. By C. Godfrey Gunther. 8vo., pp. 193, Ill., Index. Hill Publishing Co., New York, 1909. Price \$3.

This book includes a brief, clearly written, discussion of the principles underlying magnetic ore separation. The different types of machines in successful use are described and figured. Following this are chapters devoted to the concentration of magnetite ores, the separation of pyrite-

blende ores, the separation of siderite from blende, and the separation of miscellaneous ores. In each case actual practice is described and many flow-sheets are given. It is to be regretted that more figures of cost and efficiency were not available to the author. In treating a process such as electro-magnetic separation where applicability, in the present stage of technology, can only be determined by trial, costs are, however, of less immediate importance than knowledge of the limits of the process. It might well have been pointed out, though, that installation rather than operating cost is important with this process in contrast with wet concentration. The author has done well in showing that the larger expense is incurred in preparing the ore for separation. The book is well written, accurate, and will be useful.

TOPOGRAPHIC AND GEOLOGIC SURVEY OF PENNSYLVANIA, 1906-1908. 8vo., pp. 375, Ill., Index. Harrisburg. 1908.

A brief account of the co-operative survey now being carried on by the State Commissioners and the U. S. Geological Survey, including the results of triangulation and primary traverse, and of spirit-leveling, with a list of topographic maps published, and a report of progress of the geological surveys, the latter written by George H. Ashley. Mr. Ashley's contribution is of interest as being the first general summary of the results of the new work. While necessarily a progress report only, it will be of large value to all interested in the geology and mineral resources of the northern Appalachian region.

PRELIMINARY GEOLOGICAL MAP OF THE PORCUPINE MOUNTAINS AND VICINITY. By F. E. Wright and A. C. Lane. Geological Survey of Michigan. Lansing, 1909. Price 25 cents.

This map of the region now being developed by the Calumet & Hecla will be appreciated by engineers interested in copper. It is a blue-print, scale about two miles to the inch. In addition to ordinary geographic features, the fault lines and geologic boundaries are shown.

PRODUCTION AND WASTE OF MINERAL RESOURCES AND THEIR BEARING ON CONSERVATION. By J. A. Holmes. Annals Amer. Acad. Pol. & Soc. Science. May 1909.

This pamphlet deals with the production of minerals, metals, fuels, structural material, etc., in the United States. It also gives figures on the amount that is wasted. It points out the increase in the use of these materials, the need for their conservation, and the steps necessary therefor.

CONGLOMERATE FORMED BY A MINERAL-LADEN STREAM IN CALIFORNIA. By Ralph Arnold and Robert Anderson. Bull. Geol. Society Amer., Vol. 19, pp. 147-154, Ill. New York. 1908.

AMERICAN MINING CONGRESS. First Report of the Committee on Prevention of Accidents in Metalliferous Mines. 8vo., pp. 16. Denver, 1908.

ABERDEEN-REDFIELD FOLIO. By J. E. Todd. Geologic Atlas of the United States, U. S. Geol. Surv., Washington, 1909. Price 25 cents.

INVESTIGATIONS RELATING TO ASPHALT. By Robert Anderson and J. A. Taff. U. S. Geol. Surv., Bull. 380-H, pp. 17. Washington, 1909.

INVESTIGATIONS RELATING TO SULPHUR AND PYRITE. By E. G. Woodruff, U. S. Geol. Surv., Bull. 380-M, pp. 10. Washington, 1909.

INVESTIGATIONS OF THE COALFIELDS OF WYOMING. By J. A. Taff and others. U. S. Geol. Surv., Bull. 341-B, pp. 282. Washington, 1909.

THE GENERAL ENGINEERING CO., Salt Lake City, Utah, has just published the second edition of its Ore Testing Bulletin. It illustrates the new and modern machinery which has been added to the already complete plant of this concern since the first edition was published. Numerous pages of 'mill notes and data', tables, and useful information, and like matter, make the pamphlet useful as a handbook.

COMPANY REPORTS.

UNITED ZINC.

The United Zinc Companies own nearly 4000 acres of well selected lands in the Missouri-Kansas zinc district. The corporation is one of the most substantial and conservatively managed of the Boston concerns which about 1900 became interested in zinc. The outstanding stock consists of 19,566 preferred shares of a par value of \$25 each and 92,400 shares of common having a par value of \$5. The decline in the price of spelter late in 1907 forced the company to curtail operations, and the year 1908 was an unfortunate one. The gross receipts amounted to only \$59,268, of which \$9778 was disbursed as dividends. The floating debt was, however, reduced and the liquid assets increased. In general, the resources of the company consist of ore in the ground. The policy of the companies has been to more than cover the depreciation in ore reserves from year to year by the purchase and development of new property, and to do this out of earnings rather than by means of new stock issues. In pursuance of this policy, during the past three years over \$165,000 has been expended out of earnings in new land, mine development, and equipment, largely that of the Highland property, and in an investment in stock of the Lanyon-Starr Smelting Co. The Highland is a sheet-ground property near Duenweg. The development of this property and its milling equipment, which was recently damaged by fire, has cost in the neighborhood of \$100,000. In the preliminary development work about 50 prospect holes were drilled, and in over 40 of them zinc and lead were found, all at practically the same level and proving the existence of a sheet deposit underlying the whole property. Three shafts have been sunk to the ore-level, two of them being single and one a double-compartment shaft. Over 1000 ft. of driving has been done and a breast of ore opened in good shape for mining in the No. 2 shaft. The mill now being re-built will have an hourly crushing capacity of about 40 tons. It is built in two sections. The slime department is complete. When the plant has reached its maximum crushing tonnage of 800 tons per day of 20 hours (it will take about four months after the plant is started before the mine will be opened so that this tonnage can be delivered economically), it will be productive of a large and uniform revenue for a great many years.

SHWELI DREDGING.

The Shweli Gold Dredging & Mining Syndicate, Ltd., of Mandalay, Burma, has extensive holdings of placer ground and water rights near Myitstone, in the North Shan States. The managing director, A. G. Blackwell, after visiting the dredging and hydraulicking fields of California, proceeded to the property to make plans for its development. The report of the company for 1908 is mainly taken up with his statement. Apparently the placers are extensive and workable, but as results of analyses on the concentrates made in the field were not available for the report, no final estimate of values is given.

CRESCENS.

The Crescens (Matabele) Mines & Land Co., Ltd., has large holdings in Matabele land, South Africa. Since the beginning of work, in May 1905, 25,734 tons of ore, yielding 14,965 oz. gold and a little silver, had been produced up to April 1, 1909. For the last year the mining has been done by tributors, and the profit for 1908 amounted to £4591, leaving a net remaining loss of £26,612. This, however, is not so bad, since it means that the company debt has already been reduced one-half. Since the company owns 531,384 acres of ground, it has large potentialities. It is managed by the Rhodesia Exploration & Development Co., Ltd., at Bulawayo.

ROBINSON.

The nineteenth annual report of the Robinson Gold Mining Co., Ltd., gives interesting details regarding the very prosperous work of 1908 at this great Rand mine. Since production began, the Robinson has yielded over £12,082,267 and the company has paid £6,549,687 in dividends. In

1908 the working profit was £1,007,006, and £825,000 was distributed as dividends, equivalent to 30%. W. W. Mein, who succeeded Sidney J. Jennings as consulting engineer, places the present ore reserves at 4,644,376 tons. Of these, 2,788,362 tons, being on the Main Reef Leader and the South Reef, are valued at 11.3 dwt. per ton. The remainder, on the Main Reef, are put at 4.75 dwt. He states that "there appears to be no marked tendency of the grade to change in any particular direction." Within the year 630,349 tons were mined, of which 18,193 were sorted out, the 210 stamps and 3 tube-mills treating 514,757 tons, with a yield of 315,690 fine ounces, equivalent to 12.265 dwt. per ton. The cost per ton was 12s. 6.7 pence.

VILLAGE DEEP.

The Village Deep, Ltd., in 1908 yielded 428,304 tons, of which 35,100 were crushed by the 180 stamps, yielding 26s. 8.98d. per ton, at a cost of 7s. 3.73d. A reduction in costs amounting to 4s. 9.7d. per ton was effected, with an increase in profits for the year of £52,058. The capacity of the treatment plant was increased and 23,823 ft. of development accomplished. The ore reserves are placed at 1,949,267 tons, valued at 5.58 dwt. per ton by W. W. Mein, consulting engineer. A dividend aggregating £106,067 was paid, and £149,149 carried forward.

FERREIRA.

The Ferreira Gold Mining Co., Ltd., is another of the Rand properties of which W. W. Mein is consulting engineer, succeeding Sidney J. Jennings. The Ferreira in 1908 did well. The development amounted to 1306 ft.; 339,014 tons were mined, 290,770 milled, and 282,669 given secondary treatment; 170,878 fine ounces of gold were won, at a working expenditure of 18s. 7.35d. per ton milled, and a profit of 30s. 10.48d. The total profits for the year were £448,848, and two dividends, each of 150%, aggregating £285,000, were paid.

Commercial Paragraphs.

The STROMBERG-CARLSON TELEPHONE MFG. CO., Rochester, N. Y., announces that it has secured the services of Franz J. Dommerque to represent it exclusively in an engineering and advisory capacity.

FREDK. C. ROBERTS & CO., San Francisco, agents for the ABBÉ ENGINEERING CO., New York, advise that they have recently sold a tube-mill to the Florence Goldfield Mining Co., Goldfield, Nev. It is to be equipped with Ideal spiral feed.

The KEYSTONE PLACER DRILL CO., Beaver Falls, Pa., is preparing a book on 'Blast Hole Drilling with Well Drills', which is to be published in connection with the 1909 edition of its Catalogue No. 4. The company will be glad to receive drilling records and general information along that line.

The WOOD DRILL WORKS, Paterson, N. J., is distributing a booklet called 'Glimpses of the Panama Canal', which is a non-technical review of the canal by Warren Wood and Robert J. Wood. It is a 16-page booklet, containing cuts of the Gatun dam, Culebra cut, the old Santo Domingo church, and other interesting sights. It will be sent to anyone interested.

Catalogues Received.

W. S. ROCKWELL CO., New York, in its Catalogue No. 4, describes and discusses its various styles and sizes of crucible melting furnaces.

The MILWAUKEE LOCOMOTIVE MFG. CO., Milwaukee, Wis., is distributing its catalogue of gasoline driven locomotives. It is called Publication No. 100.

THE CYCLONE DRILL CO., Orrville, Ohio, in its Bulletin No. 2, just published, describes its line of small core drilling outfits, and gives complete net prices covering machine, tools, and equipment.

The JOSEPH DIXON CRUCIBLE CO., Jersey City, N. J., has issued a small pamphlet called 'The Proper Care of Belts', which contains many hints to those concerned with the proper running of power transmission belts.

EDITORIAL.

STATE Geologists were not invited to meet the Director of the United States Geological Survey in conference at Washington this spring, as has been the pleasant custom of recent years. We are left in doubt whether their appetites or their criticisms were too keen.

AT the meeting of the Western Association of Technical Chemists and Metallurgists, to be held at Denver, July 2, Professor Robert H. Richards and his brilliant wife will deliver addresses upon metallurgical and chemical subjects in which they have won distinction.

FILJ is to have a Mines Department, and Mr. N. D. Cochrane of the Waitekauri Union Mines, and for seven years Inspector of Mines in New Zealand, has been offered the position of head. Discoveries of copper, lead, gold, and silver have been made, and sugar and copra may have to yield place to ores and metals as chief exports. When the truth is known to young Americans in all its nakedness, that the Fiji Islanders are liable to take out union cards, we doubt not that the South Seas will lose their attractiveness.

TARIFF tinkering goes on in the Senate, with speechmaking under the spot-light and trading in the wings. The House has passed one bill. In due time the Senate will pass another and a painstakingly different bill. The Conference Committee will then evolve a third, which is likely to be of such strange physiognomy as to raise questions as to its parentage. Finally, if the President permits, the courts will take a hand, and in the course of some years we will discover, not whether Congress intended to revise up or down, but whether it did. In the meantime prosperity stands anxiously waiting for the cue. A delightful *fantoccini*!

OUR comments regarding the arrest of Mr. Edmund Juessen prove to have been especially well founded. In an official statement issued by the officers of the Pittsburg-Silver Peak Gold Mining Company it is pointed out that at the time charged in the indictment Mr. Juessen was not general manager. As consulting engineer he was not consulted about, nor did he have any connection with, the billion tax returns, and he had no knowledge concerning them or their contents. It is a pleasure to call attention to this explanation. There are intimations that the whole affair was to cover a 'bear raid' on the stock, and Mr. F. Augustus Heinze is mentioned in this connection. It is not easy to get the whole truth at this time. Unfortunately, American financiers and company management are not always above suspicion, and the company involved has some active antagonists. We protest, however, against mining engineers being made the victims of financial games

and stock-jobbing enterprises. The technical advisers of a company should not be subjected to arrest for any such flimsy reasons as those assigned in this instance.

LOW-GRADE porphyry is a term which has gained such currency as to be bandied about today by the man in the street. In fact, it has become a fad, and to some extent a fetich, so that the promoter of the new breed of copper wild-cats must in future cease prating of veins which assay 20 per cent; he must discourse gravely of the millions to be won from the narrow margin in a 2 per cent ore. In truth, a 'low-grade porphyry' that shows 2 per cent copper is almost rising above the level of its class.

ON THE sixth day of July a test case to determine the constitutionality of the eight-hour law applying to mines and reduction works in California will be argued by Mr. Frank J. Solinsky before the Supreme Court of the State. Mr. Fred J. Martin, manager of the Utica mine, in Calaveras county, submitted to allow his attitude to become the basis for a contest which will set at rest conflicting interpretations of the statute. He violated the law in its three chief provisions, and was arrested on each separate count. The case will accordingly determine the validity of the law so that no question can remain as to the rights and obligations of the mine operators. The points which will be settled are primarily whether the limitation to eight-hour shifts will hold; secondly, whether workmen, employed on eight-hour shifts must go to and from their working places on their own time; and finally, whether the eight-hour limitation applies to quartz-mills as well as to other metallurgic reduction works. The complaints were filed on June 6, and the Superior Court declining to grant relief, the case was appealed directly to the Supreme Court.

REPEAL of the charter for the Metal and Mercantile Exchanges in New York is unequivocally recommended by the committee recently appointed by Governor Hughes of New York to report on Wall Street methods. The published market dealings on the Metal Exchange are not based on actual sales of metal. The report states that "prices are manipulated by a quotation committee of three, chosen annually, who represent the great metal-selling agencies as their interest may appear, affording facilities for fixing prices on large contracts, mainly for the profit of a small clique, embracing, however, some of the largest interests in the metal trade." In short, the metal market is arbitrarily controlled, thus affording to the manipulators the profits of a 'corner' without the risk of corraling the commodities. Governor Hughes is a practical reformer; he obtains data first, and frames his measures in the light of known facts. By appointing this committee, headed by Mr. Horace White, he commands the confidence of the world; and perusal of the findings of these men leads to recognition of the simple principle that a trust exists whenever the law of supply and demand is artificially disturbed, and that a remedy consists in prohibiting organizations, which influence quotations, from trading in the shadow instead of the substance.

Miners' Liens.

In our news columns attention is drawn to the case of the Confidence mine, in Tuolumne county, California, where the workmen have been left unpaid since December last. Other creditors have attached the property, and the miners affirm that they are left without remedy. Our understanding of the law does not agree with this hopeless view. A mechanic's lien takes precedence over other claims, and lies against the property itself, even when the ownership was not vested in the employer of the labor. It is for this reason that cautious lessors stipulate not only that lessees shall be solely responsible for labor debts, but even require deposits as guarantees of faithful performance in this regard, so as to prevent the possibility of clouding title. The alternative protection for the owner of a leased property is to post a notice on the property itself, disclaiming responsibility for labor debts. In Alaska it has been different, and complications have resulted. Gravel mining is usually continued through the winter, the gravel being piled in dumps against the spring clean-up. Dishonest and impecunious operators, disappointed in the amount realized, have from time to time defaulted in payment of wages. As a result, time-checks can only be cashed at ruinous discounts, wages have been high, and a bitterly contested strike had to be fought. James Wickersham, the present Delegate to Congress, has proposed a bill giving miners' liens for labor on dumps and gold dust, provided the claims are filed within ninety days after the completion of work. So long as the merchant is secured by liens it is certainly fair that the miner should enjoy the same protection, and Alaskans have already learned that failure to give adequate security to the men who handle the pick merely results in piling up costs and trouble. The law of compensation admits of no evasion in this or other particulars.

Investment in Mexico.

Refutation of peril to Mexican stability, political or financial, is afforded in a striking manner by the verdict of the moneyed men of New York in promptly taking the issue of \$24,000,000 of 4½ per cent prior lien National Railways bonds, which were offered through the house of Ladenburg, Thalman & Company. These bonds were all subscribed at 95, and are now being traded in upon the floor of the Stock Exchange at about 95¼. No better answer could be given to the prophets of evil. Mexico is no longer a doubtful country; her government is established beyond fear of subversion; her financial policy is a model for the world; her banking system is more sound than that of the United States; and we could learn useful lessons in railroad control from the administration which has there been established under a representative commission, so constituted as to harmonize the diverse interests involved. Concurrently with the flotation of the new issue of prior lien railway bonds comes definite information of comprehensive railroad construction in the northern part of the Republic, closely linked with the development of mineral resources. Contracts are being let by the

Cananea Consolidated Copper Company for the building of a railroad across the Sierra Madre, giving the West Coast a northern outlet to the Mexican Central, passing on the way famous centres of silver production. This enterprise represents in effect one phase of activity related to the expansion of the International Smelting Company, whose influence promises to give a new direction to the metal market and to promote stability of production and prices. Coupled with this development under the initiative of Messrs. Thomas Cole and J. D. Ryan, is another equally important expansion of railroads in central and western Chihuahua, financed by Mr. F. S. Pearson and the powerful financiers associated with him. Meanwhile the Southern Pacific Company has opened its West Coast line to Escuinapa, 54 miles beyond Mazatlán, and the link between the eastern section in Jalisco and the present end of the track in Tepic is being closed as rapidly as the natural obstacles will permit. Information likewise comes of a new line from Guadalajara to the Pacific, traversing the important mining districts of Autlán and Ayutla, and also of an extensive system for developing the mineral resources of Oaxaca by the Mexican Southern railway, which has recently acquired the Taviche and the Oaxaca-Tlacolula lines. These are indices of the confidence of capital in the future of Mexico. Nothing so surely draws the purse-strings of investors as political insecurity, whatever be its nature. New enterprises in the United States are seriously retarded by the delay of Congress in passing the tariff bill. If there were financial or political difficulties threatening the course of Mexican progress, the sensitiveness of capital would be the first to detect it, and such investments as are being made today would be impossible.

Graft Prosecution.

Failure to obtain a verdict in the Calhoun case has distinctly set back the cause of civic betterment in San Francisco. Continued vacillation between right and wrong blunts the critical sense of the people. Procrastination in the administration of justice favors the growth of indifference to moral distinctions. Sharp, swift, decisive action is tonic. Such a bracer is needed. Can we obtain it? If so, how?

The recent trial was a flat failure. It is a dispiriting miscarriage of justice to have a case drag through weeks of acrimonious struggle, and in the end for the jury to show inability to weigh and judge the evidence like reasoning men. The jury certainly was at fault; its responsibility was shirked—a responsibility toward the accused, and another toward the public. The work of the busy city goes on apparently the same, and the people laugh. Nothing comes of these most serious charges against men conspicuous in the vital operations of the municipality; dereliction is therefore trivial, and civic duty becomes a matter of light regard. Under such circumstances the courts themselves lose influence; and the taint of weakness touches even the garments of the judge. If the matter be too weighty or tangled for the minds of jurors untrained in the law, then it were better either to give the prisoner the benefit of the doubt,

or to return a verdict of guilty and thus permit the case, in its distinctly legal aspects, to be reviewed on appeal to a higher tribunal. We need authoritative legal utterances. The present course of things only cultivates civic obliquity, and creates a public sentiment which will permit a relapse into the political debauchery of the past.

The legal contest which has just been waged has been significant in its demonstration of the need of reforms which must sweep more widely than the narrow limits of municipal politics. The degeneration of our trial-system has been forcibly illustrated in the present instance. Instead of leading to an ascertainment of fact and of the law applicable thereto, the spectacle has been that of a *corrida*—a bull-fight, to speak plainly, where skill in the rules of the game, rather than the legal merits of the case, riveted the attention of court and people. It was a battle of wits, with the judge as umpire to see that the contestants kept from playing foul—and all the while the effort was 'to hit below the belt' when the umpire wasn't looking—or when he may perchance have been casting a far glance toward electoral influences. Here is an obstacle to the administration of justice which is as serious as those absurdities of court procedure which befog the issues presented to a jury. Judges generally accept a seat on the bench because it yields an income. Ideal civic or patriotic motives are often absent, however much they may sometimes animate the firmly seated occupant of the bench. Superior Court judges, being dependent upon election, and being human, feel the need of currying favor, of winning applause, and of dodging the perils of sitting as trial-judge over cases in which the enmity of powerful corporations may be incurred. The prevalent shuffling among judges to avoid this embarrassment shows to what pitiful shifts the supposed conservators of justice are driven in order to keep on a respectable footing with their own consciences. It is not often that the elective system for filling judicial positions brings forward men of such courage as Judge J. M. Seawell of the Superior Court of San Francisco. Under him we believe that the graft cases would have been disposed of swiftly and effectively.

The admission of irrelevant testimony confuses a jury, and affords excuse for failure to perform its duty. It opens the way to mis-trial, and defeats the ends of justice, whichever side be allowed to commit the error. Subsequent instructions by the judge to disregard irrelevant testimony fail to erase the impression made, not only of the testimony itself, but of the unfairness of its introduction.

All the defects to which we have called attention were exhibited in this trial. The defense rested on a cross-examination of the prosecution's witnesses, thus revealing the weakness of both sides. It is not possible to construe this into mere failure to show probability of guilt. The fault lies in the system, and the misuse to which it can be put. Until we improve the meting out of justice by a reform of court procedure, and by stiffening the backbone of the judiciary, only the rare circumstance of trying these cases before an absolutely fearless judge can give San Francisco the moral corrective that she needs.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

CHARLES BUTTERS is in London.

J. H. MACKENZIE is at Santa Cruz.

R. GILMAN BROWN is in West Africa.

W. C. THOMAS, of Salt Lake, is in Wales.

JULIUS W. HEGELER has been in New York.

ARNOLD BECKER was in San Francisco recently.

H. J. SHEAFE of New York is in San Francisco.

C. W. HAYES is expected in San Francisco July 10.

J. A. EDE is in the British Columbia zinc district.

H. C. HOOVER has returned to London from Korea.

F. LYNWOOD GARRISON is expected in San Francisco.

NEWTON B. KNOX is expected at London from Korea.

T. H. ONNAM, of Glendale, California, is at London.

ARTHUR K. ADAMS has gone to Huron, South Dakota.

C. K. LEITH will go to the Hudson Bay region in July.

EDWARD TOMARSON, of Pioche, Nevada, has gone to London.

J. P. IDDINGS has left for an extended trip through the Far East.

S. F. SHAW will be in Pioche, Nev., during July and August.

GEORGE ALEXANDER has returned to Kalso, B. C., from Europe.

F. G. STEVENS, of Etzatlan, Mexico, has been visiting Toronto.

W. E. GORDON FIREBRACE is at New York, on his way from London to Lima.

J. C. GWILLIM is at the St. Eugene mine, East Kootenay, British Columbia.

RALPH ARNOLD has been in the Coalinga and Santa Maria oilfields of California.

F. F. SHARPLESS is at Placerville, California, and will thence proceed to Nevada.

H. P. GARTHWAITHE is on his way to Salvador, returning from a short visit to London.

H. H. WEBB and ALFRED VON DER ROPP left London on June 12, on their way to San Francisco.

W. G. ANDERSON has accepted a position with the El Favor Mining Co., at Hostotipaquillo, Mexico.

ARTHUR L. PEARSE is on his way to Juneau, Alaska, and expects to be at London early in August.

C. H. WILDMAN is superintendent for the Norwalk Mining Co., Ltd., at Michipicoten River, Ontario.

JUAN FELIX BRANDES has returned to Colorado from Europe. He will go to Mexico in the autumn.

A. C. LANE has resigned the position of State Geologist of Michigan to take a position in Tufts College.

G. S. SIMPSON, vice-president of the Butters Filter Co., has returned to San Francisco from a trip through Arizona.

W. J. ADAMS has been appointed consulting engineer for the Californian General Mining Co. of London and Paris.

WAYLAND H. YOUNG and JOHN PARK, of Oakland, have gone to Plumas and Sierra counties, California. They will go from there to Nevada.

S. E. BRETHERTON has returned to San Francisco from a trip to the properties of Friday & Lowden and the Afterthought Copper Co., of Shasta county, California.

P. C. LEAS has been formally appointed manager of the mining machinery department of the Union Iron Works, San Francisco, a position in which he has been acting for the past four months.

GEORGE O. ARCAULT has been appointed general manager for the Iron Silver Mining Co. and Leadville Co. in charge of the Colorado American Co. Mr. Arcault is a son of Philip Arcault and has been in the mining business for several years. He was formerly a partner in the Colorado American Co. and has been in the mining business for several years.

General Mining News.

ALASKA.

(Special Correspondence).—The Bourbon dredge is now in charge of A. S. Grant, of the firm of Connor & Grant, who was formerly connected with the Butte and El Oro dredging companies at Oroville.—The Wild Goose Mining & Trading Co. is now starting its summer's operations. The first elevator was started on June 9, the second is to be started on the 11th, and two more within the next ten days. In the Nome district they are getting the Seward ditch in shape, and expect to have the water from the Nome river flowing through it about the 25th of this month. The season here is a little later than in the Council district. It does not pay to put the water into the ditches till frost is out of the ground. The snowfall last winter was less than the year before, but the summer water season seems to depend more on the distribution of the summer rains than on the winter snowfall.

Nome, June 10.

The stamp-mill erected by Ed. McConnell in the Bonfield district is now running on quartz that will average over \$12 per ton of free-milling gold. The concentrate is being sacked for shipment.

ARIZONA.

COCHISE COUNTY.

A fire in the Calumet & Arizona saw-mill near the Irish Mag shaft destroyed approximately \$30,000 worth of property.

GILA COUNTY.

The Cactus Development Co. is to install a battery of 300-hp. boilers, a double-drum hoist, and a new compressor shortly. The Hamilton shaft is down 530 ft., with drifts run from the third, fourth, and fifth levels. Ore was cut at 220 ft. that averaged 2¾% copper. T. W. Hamilton is superintendent.—The Superior & Boston Copper Co. has recently paid \$100,000 cash for the Collins-Doyle property. Frank H. Probert is consulting engineer.—The Arizona Commercial Copper Co. cut a body of native silver and copper on the 700-ft. level.—The McGraw shaft of the Superior & Boston cut a body of carbonate ore at a depth of 160 ft. that assays 9% copper.—At the Superior & Globe a shaft of three compartments has been sunk 330 ft. through the diabase. P. J. Wagener is in charge of the work with a force of 28 men.—A 4-stamp mill is being erected for the Single Standard company. Assays of the ore have run between \$12 and \$142 per ton.—At the Centennial mine, which is one of the oldest workings in the district near Cameron, sinking and driving is being done under the direction of W. M. Davis and Harry Zschoegner, who have leased the mine. The Centennial shaft is down 300 ft. and cross-cuts are being run from that point. The ore is copper and silver sulphide.—At a depth of 50 ft. in the A shaft of the Chrisman & Globe mine, a 10-ft. drift has been made, and ore has been taken out that runs \$6 per ton gold, 5% copper, and carries some silver.—The National Mining & Exploration Co. has sunk the new Williams shaft 50 ft. in diabase. A hoist has been installed and the shaft will be put down to the 600-ft. level. A car of ore taken as a test shipment averaged 12% copper. F. A. Woodward is superintendent.—The shaft of the Orphan Copper Co. is down 1200 ft. and cross-cuts are being run on the fifth level. C. M. Clark is manager.—The Copper & Silver Zone mine has shipped \$1700 worth of ore to the smelter since the first of the year.

MOHAVE COUNTY.

The claims of Grant McKesson in the Riverside Mountain district have been bonded to Los Angeles people.—The big dredging plant on the Colorado river near Eldorado canyon, is completed and turned over to the dredging company by the builders. It is expected that the first work of the plant will be done early in August, it being possible to work some of the gravel banks bordering the river by that time. When the river has resumed its normal condition the big pumps will be put to work on the bar and river bot-

tom.—S. C. Bagg and associates, who have a bond on the Cyclopic mine in the Gold Basin district, have cut an excellent orebody 1000 ft. northwest of the old workings. The first lot of this ore that was taken out milled \$29 per ton.—The first dividend of the Union Basin Mining Co., the only zinc company operating in the territory, has been declared for the 25th of this month. The property operated by this company is the Golconda mine, in Union basin. This mine has been developed 200 ft. in depth, and ships one car of ore per day to the smelter.

YAVAPAI COUNTY.

The Bokaritz Mining Co., operating the Etta mine in Cherry creek, has sent to the Prescott National Bank two bars of gold bullion worth \$800.—The final payment has been made on the property of the Pittsburg-Mayer Mining Co. by F. E. Miller, of Pittsburg, Pennsylvania. The holdings of the new company comprise six claims, three miles east of Mayer in the Yavapai schist belt.—The Pocahontas Copper Queen Mining Co. has purchased a mill and is now erecting it at the Spar mine. The shaft is down 200 ft., with drifts and cross-cuts from the 100 and 200-ft. stations. W. H. Skinner is manager.—The Swiss Girl shaft of the Bauman Copper Co. is being re-timbered and will be sunk 500 ft. to the 1400-ft. level, from which point cross-cuts will be driven. Robert Campbell is superintendent.—The shaft of the Arizona-Utah Copper Co. is down 185 ft. and the vein cross-cut 20 ft. The ore assays between \$8 and \$10 per ton.

CALIFORNIA.

AMADOR COUNTY.

M. J. McDonald, who has operated the Keystone mine for the past 40 years, has sold that property to the California Consolidated Mines Co. This company is now operating the Wildman, Lincoln, and Mahoney mines at Sutter Creek, and will install heavier machinery and increase the working force at the Keystone.

BUTTE COUNTY.

The Boston machine shops at Oroville are being re-built and enlarged. The shops were partly destroyed by fire two years ago, and the dredging company had no occasion to hurry re-construction until now, when it is intended to commence the work of building another gold dredge across the river.—The Feather River Exploration Co.'s machine-shop is to be moved from Dredge to a new location in Thermalito.—The old Continental dredge, which has been operating for ten years, will be dismantled shortly, having been worn out in the process of extracting \$2,000,000 in gold from the soil just outside the city limits.

CALAVERAS COUNTY.

The Plymouth Rock mine near Jenny Lind has been bonded to San Francisco parties. At present five of the ten stamps at the mill are dropping on \$60 ore, which carries a high percentage of sulphide. The concentrate is shipped to the smelter.

NEVADA COUNTY.

A local branch of the Western Federation of Miners Union has been formed at Graniteville.—The trouble at the Idaho-Maryland has been adjusted and the miners returned to work. The drift in the east level has been run 300 ft. beyond all old workings, and the vein is from 12 to 15 ft. wide, 4 ft. of which is said to be high-grade milling ore. A raise from this level is up 90 ft., all in ore. This vein is in a territory never worked before by either the Idaho or the Maryland companies.—Martin Wallace has secured an option on several claims near Graniteville and is trying to interest capitalists to develop them.—The drain tunnel of the Gaston is in 2600 ft., with 1800 ft. remaining to complete the work. This will give 800 ft. backs on the main Gaston vein. This property is equipped with a modern 40-stamp mill. Claude Ferguson is superintendent. The water has been lowered to the 500 ft. level in the Pittsburg

PLACER COUNTY.

W. S. Fletcher, adding to the capacity of the mill at the Home Ticket, and doing other work preliminary to the development of the mine. The channel has been diked out on a systematic scale and work can be crowded when the

taking out of gravel begins. All the channel thus far opened pays.—The gravel in the El Dorado has been getting richer as the drifts are advanced. Tom Haney has leased the channel along the adit in the lower lead of the El Dorado.—Wood & Young have struck a narrow but rich vein in the Dewey.—The Anderson mine at Duncan Ridge is taking out some excellent gravel. The company is starting a new tunnel.

SAN BERNARDINO COUNTY.

A 15-ft. vein was cut by a cross-cut on the 200-ft. level of the Oro Belle mine.—A 750-ft. adit on the Oro lease of the Big Chief company cut three veins of milling ore. These have been drifted on and a quantity of \$8 to \$12 ore blocked out. William L. Foster is manager.—Cross-cuts from the 100 and 200-ft. levels of the Jumbo property have cut a 15-ft. vein. A carload of this ore averaged \$40 per ton.

SHASTA COUNTY.

The railroad depot at Iron Mountain, the saw-mill, timber-shed, and ore-bunkers at the railroad terminal were destroyed last week by fire. The Mountain Copper Co.'s loss will be close to \$8000, partly covered by insurance.—A \$2700 gold-brick was shipped to the mint by the Black Tom Mining Co. near French Gulch. Frank Eichelberger is manager.

SIERRA COUNTY.

H. L. Englebright and A. A. Charonnat have secured a bond on the Golden Star placer mine, situated in the Alleghany mining district.—A new 1200-ft. drainage tunnel is being driven at the Brandy City gravel mines. George F. Taylor is superintendent.—Work on the tunnel to tap the channel of the Secret Canyon Mining Co. has been resumed.—The Sixteen-to-One mine cut another rich portion of the ore-shoot in a raise. One thousands pounds of the ore is estimated to contain \$50,000 in gold.—Two specimens were taken from the Rainbow mine that were valued at \$1900.—The El Dorado Mining Co. has driven 40 ft. on the vein and the shoot is still high-grade.—A drift has been run 150 ft. along a 5-ft. vein of \$20 ore in the Chipps mine.—There are between 35 and 40 men taking out gravel at the Bellevue mine, between St. Louis and La Porte. This is rich, but the ground being soft makes its extraction difficult.—The Sovereign Mines Co. owns the Papoose mine in Jim Crow canyon and the Sovereign in Ladies canyon. At the Papoose a 15-stamp mill is running steadily on good ore. The vein is 10 ft. wide and is worked through a tunnel above which there is about 200 ft. of backs. A 10-stamp mill and compressor is to be installed at the Sovereign as soon as the machinery can be hauled in.—Frank Dillon has an option on the Comet mine. A 200-ft. tunnel cuts a 20-ft. vein which has been driven on for 300 ft. There is a 5-stamp mill on the property.

TCOLUMBI COUNTY.

The Confidence Consolidated mines, held under a lease and bond the past two years by Los Angeles people, with W. P. Cunningham part owner and manager, has closed down. The Electric Power Co., furnishing power to the mine, attached the pumping plant for power bills. The mine has not had a pay-day since December 1908, and the miners find the financial standing of the company in such shape that they cannot collect their wages.

YUBA COUNTY.

The new electric compressor plant at the Snowden Hill gravel mine above Camptonville is about ready to be put in operation. The pipe-line is nearly finished, and the dynamo set. The company is now engaged in building 500 ft. of sluices that will be used for washing the gravel, which is free and does not require milling.

COLORADO.

BRICKENRIDGE COUNTY.

The Wellington Mines Co. is keeping four teams busy hauling ore and concentrate from the property to Brackenridge for shipment. By so doing the regular output of 200 tons per month is being maintained. A siding about 50 ft. long has been built for the company's use.

berlain-Dillingham sampler.—The Reliance dredge is now being repaired. A new bucket-line with two hardened-steel five-ton tumblers and ladderway are being put in. It is expected that about a month will be consumed in the work of putting the boat in good condition for a year's steady operation.

CLEAR CREEK COUNTY.

(Special Correspondence).—E. J. Butts has a big force of men at work on the Columbia and Eureka mines, situated on Silver mountain. The two adits are being cleaned out and re-timbered, and will be advanced to open new ground. In the upper workings there is exposed a streak of ore that is from 2 to 4 in. wide, and assays from 3 to 13 oz. gold per ton.—Okun Bros., owners of the Scott property on Republican mountain, sent a shipment of 20 tons of silver-lead ore last week and received a settlement of \$43 per ton.—Work is under way in the Sporting Times property on Alpine mountain. A. H. Colburn, the owner, has started cross-cutting east from the Moore vein to intersect the Sporting Times vein. Driving will be resumed upon the Moore vein on a streak of ore that is from 6 to 8 in. wide and runs about 2 oz. gold, 14 oz. silver, and 61% lead per ton.—A carload shipment of smelting ore was made last week from the Gold Quartz property at Alice, and returns of \$30 per ton in gold were realized. W. A. Maxwell is manager.—The Lombard mill is crushing from 40 to 50 tons of ore daily, and a clean-up of the plates made the first of this month resulted in nearly \$9000 gold. H. I. Seeman, of Denver, is manager.—The electric plant of the Two American Sisters M. M. P. & E. Co. has been leased to the Georgetown Power Co. for a period of five years. Wires have been strung to Empire and electricity is being furnished to the residents and mine operators of that place. J. F. Eidy is manager.

Georgetown, June 19.

GILPIN COUNTY.

The electric plant at the Perry mine of the Oak Hills Coal Co. is now ready for regular operation, 5000 ft. of heavy transmission line having been hung underground. Two motors have been placed on the tipples to handle the cars as they come up out of the mine, and the small hoists and coal-cutting machines will be operated by electricity.—The A. K. R. Gold Mining Co. has cut the ore-shoot on the lower level of the Smuggler mine. The stamps are dropping on ore that mills about \$20 per ton, with a concentrate that is worth from \$50 to \$90 per ton. G. M. Ashmore is manager.—The Gilpin Mining Co. has resumed work on the Little Gold Dirt mine at Gilpin.—A force of 10 lessees in the Perigo, near Rollinsville, is taking out a good deal of milling and some smelting ore, the latter running about \$50 per ton at the sampling works. The milling ore is stored and the mill run on lots of about 1000 tons. The concentrate runs about \$45 per ton.—The Sherman & Macon Mining & Milling Co., operating in Silver Creek, have shipped a lot of ore to the Chamberlain sampling works during the past week, as well as to the Fifty mill in Black Hawk, both lots being for test purposes to enable them to ascertain the content of the vein which they recently cut in the tunnel workings.—F. A. Burnell, of Denver, has made arrangements to run the ore taken from the Luella B. mine on Perigo hill through the Daisy mill. A 5-ft. vein has been opened on the property by two shafts, 130 and 70 ft. deep.

OURAY COUNTY.

The Ouray Mining & Milling Co. has commenced work on its Highland Chief and Fredonia mines. S. O. Rickard is in charge of the work.—A new pipe-line for water-power has been laid to the mill at the American Nettie mine.—The raise being made from the level of the main working tunnel of the Thistledown mine on Mt. Hayden to the ore-shoots encountered in the upper workings has cut good ore for the last 30 ft. Two shoots of ore have been cut by this raise.—Work has been started on the Gray Hound group near Ironton.—The Pony Express is shipping high-grade ore regularly.

TELLER COUNTY.

The Elkton Consolidated Mining & Milling Co. announced the regular bi-monthly dividend of 1c. and an extra divi-

dend of $\frac{1}{2}$ c. for June 24.—Four sets of lessees mining ore from the surface deposit on the Four Queens and White House claims of the Stratton's Independence, Ltd., estate on Battle mountain loaded several teams last week for the valley mills. This surface ore is reported carrying gold from 1 to 7 oz. per ton.—A car of ore was shipped by the Victor-Colorado Mining Co. from its lease on the Rigi mine on Battle mountain.—Lessees are shipping ore from the Papoose Gold Mining Co.'s Guess claim on Squaw mountain. The ore is being mined from the May B. vein.—The north half of the Four Brothers lode mining claim on Beacon hill has been purchased by Willis B. Cauble, of Peoria, Illinois, one of the directors of the Iowa Mining & Leasing Co.—A shipment of two cars of ore from the Deadwood mine of the United Gold Mines Co., mined at the 250-ft. level, was made last week, and the returns received were on the basis of \$26 per ton.—Operations on company account have been commenced at the No. 1 shaft of the Dante Gold Mining Co., and the mine will shortly be re-equipped with a modern mine plant. The company has purchased a powerful 10 by 14-in. hoist and will equip the shaft for a two-ton skip.

IDAHO.

BLAINE COUNTY.

The Comet group in Scorpion gulch has been recently purchased by J. George Arkooosh of Bellevue. The vein has

Map of Idaho.

been traced for 1000 ft. on the surface, and 600 ft. of 'backs' shown by lateral work. The average assay returns have been lead 76%, silver 120 oz., and gold \$16 per ton.

IDAHO COUNTY.

The Elk City Dredging Co. has purchased the Golden Seal and Golden Seal Extension placer claims on the American river and have started construction work on a dredge. I. B. Hammond, of the Hammond Construction Co., will have charge of the work.—A saw-mill is being erected on the Buckhorn group of mines on Thunder mountain and later a 3-stamp mill will be installed.—A new shoot of ore has been cut on the property of Charles J. Shaddock near Orogrande.

OWYHEE COUNTY.

A 6-ft. vein with a $2\frac{1}{2}$ -ft. pay-streak was cut by the adit of the Berg mine at Rooster Comb. H. B. Benson is in charge of the work.—A 15-ton mill has just been completed by E. S. Stuart for the Gold Crown mine at Oreana.—A 50-ft. shaft has been sunk on the vein of the Gold Nugget mine and a 40-ft. cross-cut run to intersect a parallel vein. C. M. Sweatland is in charge of the work.

SHOSHONE COUNTY.

On 28 tons of ore in a recent shipment from the H. E. M. mine, near Wallace, the smelter assay was lead 55.2%, and silver 18.1 oz. per ton. Russell F. Collins is directing the work.—The cross-cut tunnel on the Great Northern Co.'s mine near Burke has been driven 400 ft., and has cut chlorides assaying 14 oz. silver for the last 80 ft. Ed. Eisman is manager.—Twenty-six inches of rich galena ore has been struck on the 600-ft. level of the Corrigan mine, belonging to the Federal Mining Co., west of Wardner. Beside the solid ore there is a large quantity of milling ore.

MICHIGAN.

The Wyandot has opened the new 35-ft. amygdaloid lode cut by the exploratory cross-cut east at the 700-ft. level, from the hanging wall to the foot-wall. This lode lies considerably over 1000 ft. east of the older workings in the Winona lode, and well into the horizon of the so-called Lake lode.—Operations in the Caldwell shafts of the La Salle Co. continue with rather discouraging results, and in all probability one of these shafts will be abandoned and a new shaft started farther north in the direction of the Tecumseh shaft of the company, where first-class copper ground is being opened at several levels. The other Caldwell shaft will be deepened in an effort to get out of the shattered zone in which both are opened.—The New Baltic Exploration Co. has completed the first diamond-drill hole and has rigged up 500 ft. to the westward, where a new hole is being put down at an incline.

NEVADA.

CHURCHILL COUNTY.

Another strike was made in the Gold King Co. mine at Jessup on the 150-ft. level. The ore is of the picture-rock variety. On the Mohawk claim the rich shoot is opened for 60 ft., and the Ellis lease No. 1 is in 2 ft. of ore carrying a high percentage of horn and ruby silver.—The White Canyon Mining & Milling Co., under the superintendency of Joseph Mackedon, is encountering some very rich showings on the 200-ft. level, where a cross-cut has been run 28 ft. to cut the vein.—The Stewart Mining & Leasing Co. has resumed operations under the superintendency of A. D. Le Roy.

ESMERALDA COUNTY.

The output of the mill of the Goldfield Consolidated Mines Co. has been increased 35 tons per day.—The Great Western mine at Hornsilver has changed hands and will be re-opened shortly. The company will install new machinery and develop the mine on a larger scale.—A 5-stamp mill is being erected for the Mammoth Mining Co. on Gold mountain. P. Jubien is president of the company.—The blowing in of the smelter at Luning has done much to revive that district.—The Luning Gold Mines Syndicate, under Robert B. Todd's management, shipped a carload of high-grade ore.—The old Hidden Treasure, under the title of the Nevada Silver Leaf Co., is being developed again. J. H. Hartwick is manager.—The Lotta is being opened again after several years idleness, by George I. Wright.

HUMBOLDT COUNTY.

The winze 100 ft. from the portal of the adit of the Seven Troughs Trio Co. cut a body of ruby silver.—The Florence lease is still in an excellent body of silver ore.

LANDER COUNTY.

(Special Correspondence).—The Austin Manhattan Co. is actively pushing work on its holdings, and before winter expects to be producing on a large scale. The cutting of a station at the junction of the main tunnel and the Frost shaft is progressing rapidly, and later on the Lander Hill shaft will be opened to the lower levels. The party of

Austrian-Swiss engineers who recently examined the mine express themselves well pleased with the showing, and it is likely that the property will be taken over by the people they represent.—Colvan & Co. have opened a rich shoot of ore at a depth of 100 ft. in the Roosevelt claim. Assays run from \$40 to \$150 per ton.—Active work has started at the Patriot mine, which was formerly a good producer.—At the Grand View a gasoline engine and other equipment is being installed. Good ore has been opened and the management is preparing for active work on a large scale.—Considerable prospecting is going on in this district, several old properties are being re-opened, and the camp generally is more animated than for some time past.

Austin, June 19.

LINCOLN COUNTY.

The adit of the Rives mine cut the old workings of the Fetterman and disclosed an excellent orebody. The vein was exposed in the Fetterman for 200 ft.—The Atlanta group at Silver Park has been bonded to Elmer Bray, R. S. Baverstock, and M. D. Rochford. The property is a low grade ore and will be worked on a large scale.

NYE COUNTY.

The output of the quicksilver mines at Berlin in Ione valley is 600 lb. of mercury per day.—The placer operations in the Manhattan gulch during the past week show a continuance of the rich pay gravel, and a number of new shafts have been started for bedrock. On a majority of the properties electric power will be used.—The shaft of the Morning Star cut a 2-ft. vein at a depth of 125 ft. that assays over \$30 per ton.—On Union No. 9 all machinery has been ordered for equipping the Lamb lease with a 75-hp. electric hoist, air-compressor, and pumps.—A new strike has been made on four claims located by C. F. Smith, which are situated four miles southwest from Milletts. The property has been bonded to Nels Paulsen, manager for the Lehigh-Antelope Leasing Co. It has a vein from 10 in. to 2 ft. wide, and assays taken on the surface for a distance of 200 ft. run from \$20 to \$186.

STOREY COUNTY.

The Golden Gate mine is being re-opened under the management of Heber Holman. Machinery is being installed and the shaft will be sunk 600 ft. to the level of the Sutro tunnel.

WHITE PINE COUNTY.

The cross-cut from the 1000-ft. station of the Giroux shaft has been driven 750 ft., and a raise started for the five-compartment shaft. The company will start sinking from the surface and will sink and raise from the 700 to connect with the workings from the 1000-ft. level and the surface. Four drills are being run to prospect the ground round the Bunker Hill shaft.—The Nevada Consolidated is now cutting for a new top bench at Copper Flat. This cut is taking it near the top of the hill.—At the Cumberland-Ely the drill on the Puritan has been closed down temporarily. The Veteran mine production is keeping up, and such development work as is being carried on is giving good results.—The Ely Central is to prospect its ground with churn-drills. O. A. Turner is president of the company.—The Boston Ely has stopped cross-cutting the 800 and is sinking to the 900-ft. level, where they will again start cross-cutting.—The Coppermines property is confining its work to churn-drill exploration.

NEW MEXICO.

GRANT COUNTY.

At Silver City last week the Manhattan-Asiatic-Aztec group of mines of Pinos Altos was sold to satisfy a judgment. The property was bid in for \$26,000 by Bernard Greenholder, of St. Louis, representing Nathan Frank and Selma Rothschild. A Boston syndicate, headed by Francis E. Young, Inc. bought the Cleveland group of mines, eight miles north of Silver City. George H. Utter, the owner, received \$200,000 for the property. The Cleveland group contains copper and zinc.

LEWIS COUNTY.

The Commercial Metal Co. is about to develop an exten-

sive deposit of ore on the west slope of the White mountains, six miles southwest of Carrizozo. The company has a large body of copper-lead ore.

M'KINLEY COUNTY.

The Crescent Oil & Land Co. has shipped drilling machinery from Oklahoma for use on its claims eighteen miles northeast of Gallup.

SOCORRO COUNTY.

The Top mine in the Mogollon district has been sold by the Top Mining Co. to a syndicate which will organize the Top Development Co. The Top has a 270-ft. shaft and lies between the Last Chance and the Confidence mines.—At the Little Fannie mine of the Socorro Mines Co. a cyanide and amalgam plant has been installed, power for which is generated from a fall 12 miles away. The mill at present is treating 60 tons per day with an extraction of 89%. A new 150-ton mill is being built, as well as a 600-kw. hydro-electric plant.

OREGON.

BAKER COUNTY.

The Hammond Pony Dredge at Gold Center is ready for operation. It is mounted on a turntable 14 ft. diam. carried on an eight-wheel car. The machine revolves through a horizontal angle of 90° when in operation, making a cut 50 ft. wide at the bottom. The buckets are 2 cu. ft. capacity, and the speed is 20 to 30 buckets per minute.—A contract has been let to drive a 250-ft. adit on the Gold Coin property in the Greenhorn district.

GRANT COUNTY.

The Dixie Meadows Mining Co. has started its mill near Prairie City after five years idleness.

JOSEPHINE COUNTY.

A new corporation has been organized in Grants Pass called the Old Glory Mining Co., with C. L. Mangum as president. The property is situated on Silver creek, 20 miles west of Galice, in the vicinity of the recent rich discovery of Brazill and Robinson on the same creek, and consists of four lode and two placer claims.—The Greenback mine, 20 miles north of Grants Pass, which was shut-down a year ago, is soon to be put in operation again by its old superintendent, Cary W. Thompson, who has taken a bond and lease on the property, and will work it as soon as the mine can be re-timbered and some dead work done. There is a 40-stamp mill on the property and a first-class cyanide plant. This mine has paid to the shareholders \$1,200,000.

UNION COUNTY.

John Hughes, of Susanville, has sold the Ophir property in the Summerville district to Thomas S. Kennersly and Edmond R. Willets, of Trenton, New Jersey, for \$50,000. A shaft is down 180 ft. and the new owners intend to sink another 100 ft. and drift on the vein.

UTAH.

BEAVER COUNTY.

A car of ore shipped from the Cave mine was settled for on the basis of 17.5% copper, 5 oz. silver, and \$2 gold per ton.

JUAB COUNTY.

Two cross-cuts are being run on the Sioux Consolidated property. One of these is being driven toward the east from the 450 and the other is headed toward the original territory of the Sioux from the 200-ft. level. The mine ships about 14 carloads of ore per week.—At the Centennial Eureka mine the work of cutting out a station upon the 2260-ft. level has been completed and drifts will be run from that point. The mine is shipping about 45 cars of ore per week. R. A. Brown is superintendent.

SALT LAKE COUNTY.

Five cars of ore will be the total amount of ore shipped by the Bingham Central Standard property this month. A portion of this comes from the Mountain Maid tunnel.—The Alta mine is to be re-opened under the direction of R. J. Jarvis. The adit will be run to cut the lead-silver vein on the property.

WASHINGTON.**FERRY COUNTY.**

The McKinley Mining Co. is shipping from its property in the Orient mining district. The ore is being mined from a 7-ft. vein.

CANADA.**BRITISH COLUMBIA.**

The contractors have commenced the task of deepening the shaft from the 900 to the 1200-ft. level of the Josie mine of the Le Roi No. 2 Co.—The Centre Star group of the Consolidated company continues to yield a good tonnage of ore, the output for the week being 3690 tons. The War Eagle is developing in a satisfactory manner, the latest find being the uncovering of an ore-shoot on the eighth level. The surface of the Enterprise is being prospected as a preliminary to underground explorations from the levels of the Idaho.—On the I. X. L. an adit is being driven along the vein and the high-grade shipped to the smelter.—A large shipment of silver was made from the British Columbia Consolidated Co.'s smelter at Trail to Hong Kong, China, comprising 54 bars which averaged 1025 oz. each. The silver will be refined for the Hong Kong & Shanghai bank at Hong Kong. There was about \$55,000 worth in the consignment.—The Alberta Railway & Irrigation Co. is erecting a big steel tippie and installing heavy machinery at No. 6, a new mine, situated about four miles from Lethbridge.—At the Corbin mine, on the south fork of Michel, the entry is in a big mass of coal, up to 160 ft. in thickness. The main tunnel is in 1200 ft., and 300 tons of coal is being shipped daily.—The St. Eugene is producing between 500 and 600 tons of lead-silver ore per day, nearly all of which is concentrated in the mill.

An \$8000 gold brick was brought to Nelson from the Nugget mill during the week. This represented a 20-day run at the little mill. An English mining syndicate that is driving a tunnel on the Bell property is making an effort to secure the Lucky Shot claim at Phoenix. A strike is reported from the Rambler, West Fork, assays taken on the vein showing that it carries 980 oz. silver per ton.—At the Phoenix Amalgamated property of the Consolidated company work has been started on the tramway that will carry ore from the mine to ore-bins at the railway siding. The force at the Snowshoe mine of this company has been increased and shipments will be somewhat heavier in the future.

The 5-drill compressor, boiler, and engine of the Iron Cold Mining Co. has been purchased by the Inland Empire Co. and will be installed at the mine. It is the intention to sink to the 300-ft. level on the vein and drift till there is sufficient ore blocked out to warrant the building of a reduction works. S. F. Griswold is manager.

ONTARIO.

The King Edward mine cut a 3-in. vein of silver ore in a raise from the 150-ft. level.—An 8-in. vein of silver ore was intersected by a cross-cut from the 65-ft. level of the Silver Cross mine at Cross lake.—The Blackburn mine north-east of Miller lake has opened a number of leads on the surface and has started sinking.—The Paymaster mine at Sasaginaga lake has cut three veins in the cross-cut from the 115-ft. level.—The La Rose Consolidated Co. has acquired the Lawson mine. A double-compartment shaft is being sunk to the 80-ft. level to connect with the Silver Leaf.

QUEBEC.

J. E. Hardman, of Montreal, was in Thetford recently looking over some asbestos ground.—The Montreal fiscal agents of the Compton Gold Dredging Co. having failed to make good on their agreement to provide funds for a dredge by May 1, Kennedy & House, of Beebe, are now calling for the return of their property, as other parties are ready to take it up and put on a dredge this season. It is reported that the Eustis people are about to re-open the nickel property at Bromton lake. The asbestos merger and the sale of some prospects has caused the prices of asbestos property to advance beyond their normal value. The E. J. Canada Smelter Co., which has an option on J. McDonald's copper mine in Woodson, is sinking a new shaft. The Nichols Chemical Co. of Chatham is making

important changes in its nitric-acid plant.—The John Armstrong farm, about two and a half miles east of Danville, has been leased to a party associated with F. T. Savoie, of Plessisville, who will prospect it for asbestos.

MEXICO.**JALISCO.**

The Moctezuma Mining Co. is now being organized in the States to re-open and develop the old Argentina mine in the Ayutla district. Juan M. Quintero, of New Orleans, and James H. Lowes, of Indianapolis, Indiana, are among those interested in the new enterprise.—The St. Joe mine, near the town of Ayutla, has been sold by Louis C. Frey, Jr., to G. M. Anderson, of Montana. The mineral land amounts to nine pertenencias, and the ore is copper-silver.

MEXICO.

The Compañía Mexicana de Petroleo 'El Aguila', South America, has been formed with a capital stock of \$25,500,000 to acquire the concessions for the development, exploitation, and marketing of native crude and refined oils, as well as other kinds of oil products held by the firm of S. Pearson & Son, Ltd., Oil Fields Department. The company is headed by Governor Guillermo de Landa y Escandon, as president. The concessions secured by the new company cover all the holdings of the Pearson Oil Fields Department north and west of an imaginary line drawn about 19° longitude west from Washington and extending from Veracruz in an almost direct line south to Puerta Angel, on the Pacific Ocean and in the State of Oaxaca. It includes the Dos Bocas field and such rights as the house of S. Pearson and Son, Ltd., acquire by contract from the Oil Fields of Mexico Company.

NUÉVO LEÓN.

At a recent meeting of the stockholders of the Cia. Carbonifera Agujita, the report for the year 1908 showed a decrease in the coal output, but an increase in the coke production. There were 200 ovens working continuously.

OAXACA.

E. P. Keevil, owner of rich mica deposits in the State of Oaxaca, has gone to the City of Oaxaca, where he will take personal charge of his interests.—Agents of the Westinghouse company, it is said, are at present in the Republic with the intention of purchasing mica lands. The General Electric Co. has already purchased valuable deposits.

SONORA.

(Special Correspondence).—The May production of the Greene Cananea Copper Co. was 3,851,796 lb. copper, 85,000 oz. silver, and 506 oz. gold. The blast-furnace treated 50,638 tons of charge exclusive of coke, and the reverberatory 7222 tons, of which 5780 tons was flue dust. The blast-furnace charge was made up of 18,680 tons of first-class ore, 20,430 tons of concentrate, and 3200 tons of reverberatory and blast furnace matte with the fluxes and chips. During May all the reverberatory matte was sent to the blast-furnaces, and a portion of the blast-furnace matte was re-fed. This month no blast-furnace matte has been re-fed. The complete costs for May are not yet out, so that it is not known whether the experiment of re-feeding a portion of the blast-furnace matte was successful or not. The concentrator handled 67,896 tons of ore during the month. The coke consumption for awhile has been down to 8% of the charge, which is unusually low, running as a rule above 10%. The June production will be not over 3,500,000 lb. of copper. For the first ten days of the month only four furnaces were in blast; since then five, and the sixth will be added in a few days. The average production for the first 15 days of June was 49.6 tons of copper. The reason that only the four furnaces were in operation the first part of the month was because the ore reserve on the spreading beds was too low, but is now well ahead again. At present there is a larger percentage of concentrate on the spreading beds than formerly, averaging about 45%. The concentrates, which is classified separately at the two groups of mills, runs about as follows: Cananea Consolidated, 6% copper, Cananea, 9%, with a ratio of concentrate for the respective groups of ores of three to one and six to one.

Cananea, June 19.

Special Correspondence.

MEXICO.

North Mexican Trunk Line.—Cole-Ryan Building Railroad.—Pearson Interests.—Southern Pacific Extension.—Guadalajara-Chamela Road.—National Railway Bonds.—Matamoras Bridge.

It has been announced by L. D. Ricketts, general manager for the Cananea Consolidated Copper Co., that the company will begin construction at once of a railroad through the northern part of the States of Sonora and Chihuahua, Mexico. The Mexican Government has granted the Cananea company four concessions for the construction of the road, the sections being as follows: (1) From Del Rio; near Cananea, east to a point on the line between the States of Sonora and Chihuahua, touching the international line at Agua Prieta opposite the city of Douglas, Arizona; (2) from Del Rio to Imuris, a station on the Sonora railroad; (3) from the point where section No. 1 ends on the Sonora-Chihuahua line to a point on the Rio Grande, Sierra Madre & Pacific railroad at or near Guzmán station; (4) from Guzmán station east to a point on the Mexican Central railroad. The new road is to be constructed in a substantial manner with 80-lb. rails and with ties and timber creosoted. The line will run through the Sierra Madre, giving means of transportation for a large quantity of timber, the demand for which is good throughout the entire southwestern mining region.

For some time there have been rumors of the contemplated construction of a large custom smelter at Douglas by the Cole-Ryan interests. This new railroad, which will run through Agua Prieta, just across the international line from Douglas, adds to the probability of such a smelting plant being erected, although nothing has been stated by Dr. Ricketts in relation to it. An advertisement for bids by contractors is published in the Bisbee and Douglas papers, stating that "under concessions from the Government of Mexico the Cananea Consolidated Copper Co., S. A., is building a railroad across northern Mexico. Bids are requested on grading of same. For full particulars, profiles, specifications, directions for bidding, and other information, apply at the office of the company at Douglas, Arizona."

As previously noted, the Pearson interests have taken control of the Chihuahua & Pacific railroad, which is a necessary link in the Kansas City, Mexico & Orient line to Topolobampo in Sinaloa. The present terminus of the C. & P. is at Tomósochic, whence the Sierra Madre & Pacific prolongs communication to Madera in the heart of the great range, not far from the celebrated mines of Batopilas. The latter road, now in the grasp of the Cole-Ryan group, was located through the initiative of that fallen idol of Sonora and Arizona, W. C. Greene. The titles to the holdings forming part of this enterprise were recently investigated with great care by Walter Gow, of Toronto, Ontario, who is a vice-president of the Mexico Northwestern Railway Co., and attorney for that corporation. He was assisted by Luis Rivas y Cervantes, of Mexico City, and Joaquín Cortazar, of Chihuahua.

Work on the Southern Pacific branch road (Cananea, Rio Yaqui & Pacific) is progressing at a rapid pace. The town of Acaponeta, Tepic, was reached on June 15, and the rails will reach the great canyon of the Santiago (or Lerma) river by August. It is stated by William Hood, chief engineer, that a 1½ grade may be adopted, which will increase the cost \$8,000,000. That would indicate a determination on the part of the Harriman interests to dominate the carrying trade of northwestern Mexico. Low operating costs on the main trunk line to the Plateau industrial, and smelting centres, will admit of diverting traffic by branch lines from the western slope of the Sierras. The last section accepted by the Government was from Mazatlán to Escuinapa, 87 kilometres, making a total of 855 kilometres from Guaymas (539 miles), on which the cash subsidy has amounted to \$10,687,500.

The Kansas City, Mexico & Orient railroad is making its lower end of the trunk line for the main

tain section in Mexico is languishing. The gap there is only 75 miles in length, but it involves the most formidable construction, with a great many tunnels. It is estimated that the cost will be \$100,000 gold per mile.

A new railroad company has been organized by French and English capitalists to construct a line from Guadalajara, the capital of Jalisco, to Chamela. Governor Ahumada has announced that the State will give a subsidy of \$4000 per kilometre. The road will connect with the Ameca branch at La Vega, and will provide the Ayutla and Atlán mining districts an outlet, and at the same time will open a rich agricultural region. This would give Guadalajara a third rail route to the Pacific, and it is believed that it will constitute a valuable feeder for the Government 'merger system.'

The National Railways have just issued, through Ladenburg, Thalmann & Co. of New York, \$24,000,000 prior lien bonds, bearing 4½%, ranking ahead of the \$160,000,000 authorized general mortgage 4% bonds, which latter are unconditionally guaranteed as to principal and interest by the Mexican Government. The prior lien bonds constitute part of the total authorized bonded indebtedness of \$225,000,000, of which \$89,225,077 has already been issued. The railroad earnings in Mexico have been steadily increasing, the net product on the State-owned and State-controlled lines exceeding \$2,000,000 per month. C. R. Hudson, vice-president of the National Railways of Mexico, states: "Business generally over the Republic is looking up, and in all the years I have been in Mexico, I have not met in such a short time so many people, both from the United States and Europe, as are now here looking for investments. It seems to me that they can find them all right, on account of the diversity of what we have within the borders of the country."

The International Railway bridge at Matamoras is now being constructed, the site having been agreed upon between the engineers of the Mexican road and those of the St. Louis, Brownsville & Mexico on the American side of the line. The selection of Brownsville as the site is considered as conclusive evidence that the Gulf Coast railroad line to Tampico has definite prospects of earlier construction. It is believed that the latter line will be constructed by Harriman interests, and in the same connection it is rumored that the Harriman people will bear a portion of the expense of the construction of the Brownsville bridge.

LONDON.

Briseis Tin.—Ringarooma.—Oroya-Brownhill.

The report of the Briseis Tin & General Mining Co. for 1908 shows that the life of the Briseis tin mine in Tasmania is going to be rather longer than was originally estimated. At one time it was feared that the gravels would be exhausted by the end of 1908, but it has since become certain that there is enough left for the whole of 1909, and perhaps for a third of 1910 as well. The year's output was 768 tons of metallic tin from 1048 tons of black tin, which were recovered by washing 435,100 cu. yd. of gravel. The other property, 'No. 1', which is worked by the Briseis company for other owners, yielded 252 tons of metallic tin from 346 tons of black tin produced by washing 104,200 cu. yd. of gravel. Of this output the owners of 'No. 1' took 106 tons, and 146 tons went to the Briseis company. Consequently the latter company sold altogether 914 tons of metallic tin during the year, which was very near the figure, 910 tons, in 1907. The receipts were £121,814, as compared with £151,222 in 1907, relative figures which show at a glance the fall in the price of the metal. The net profit, after allowing for depreciation, taxes, etc., was £58,360, and £45,071 was brought forward from the previous year. The dividend distributed in 1908 was £60,000. The other properties belonging to the company are the adjoining Ringarooma and some new gold gravels in Victoria. Of the Ringarooma, the directors unfortunately have to say that systematic sampling has given vague results. During the year work has been confined to removing the overburden, and before long it is hoped to make a start on washing the tin gravels underneath. It will then, by working on a

large scale, be possible to tell what they are worth. Prospecting on the gold gravels in Victoria has yielded fair results and the options have been exercised.

The Oroya-Brownhill mine in West Australia is another example of a mine lasting longer than was expected. It will be remembered that this big producer suddenly fell off owing to the nature of the ground quite unexpectedly changing. At one time there seemed little hope of the ore lasting longer than the end of 1908, but later on it was announced that it would be possible to maintain a regular output until June of this year. More recent advice shows that it is probable that the life of the mine may be extended until the end of the year. During 1908, the mill treated 122,855 tons and the yield was 40,595 fine ounces, the average being 28s. per ton, while the working costs were 17s. 10½d., which is a reduction of 1s. 10d. as compared with the previous year. In addition to such ore reserves as are left, the company also owns some 500,000 tons of old slime residue which is being worked over again by a new slime plant. About 20,000 tons per month are being treated in this way. The extraction is estimated at about 5s. 9d. per ton, and the expenses 2s. 2d. per ton, so there is a total profit in sight of nearly £80,000. The other leases taken over in the neighborhood by the company do not appear to be promising well at all, and the hopes of the company are now centered on Central America. C. S. Herzig has been in that country and has acquired the La Leonesa mine in Nicaragua and has also obtained a favorable option on the Babilonia mine in the same State. These two properties are opening up well and the shareholders should feel fairly comfortable. So also should Herbert C. Hoover, who, as managing director of the company, has had the responsibility on his shoulders of finding a new property.

WASHINGTON.

Zinc Tariff. — Coal Imports. — Petroleum Production. — Oil Lands.

The zinc schedule of the tariff bill has at last been settled by the Senate, after a most spirited contest. As it passed and as it will undoubtedly appear, it is as follows: "Zinc-bearing ore of all kinds, including calamine, containing less than 10% zinc, shall be admitted free of duty; containing 10% or more of zinc and less than 20%, ¼c. per lb. on the zinc contained therein; containing 20% or more of zinc and less than 25%, ½c. per lb. on the zinc contained therein; containing 25% of zinc or more, 1c. per lb. on the zinc contained therein. Zinc in blocks or pigs, and zinc-dust, 1¼c. per lb.; in sheets, 1¾c.; in sheets, coated or plated with nickel or other metal or solutions, 2c.; old and worn-out, fit only to be re-manufactured, 1c. per lb." The schedule proposing a duty on petroleum has not yet reached the Senate. The Finance committee has, however, reached an agreement which provides for a duty of ¼c. per gallon on crude oil and 25% on the refined, and probably on petroleum products. The duty on bituminous coal has not been definitely agreed to, but the rate will probably be at 50c. per ton. The duty on slack or culm will be 15c., as under the present law, but there will be provided a definition of what constitutes natural slack, and only that grade of slack will be admitted under the lower rate. The House made the duty on coal 67c. per ton, without reciprocal arrangement. The need for the amendment defining slack was explained to the Senate the other day by Stephen B. Elkins, of West Virginia. It seems that in loading the Nova Scotia coal into the railroad cars it dropped from an unusual height. This broke up the coal considerably. Then, in unloading it into the boats to take it to Boston, it was passed through a tube 60 ft. long, with breakers. This also broke up the coal, so that by the time it reached Boston it would nearly all pass through a half-inch screen, and therefore most of it was set down as slack and paid only 15c. per ton.

The production of petroleum in the United States in 1908 has just been given out by the United States Geological Survey. The total production aggregated 179,572,479 bbl., valued at \$129,706,258, an increase in quantity of 8.11% over 1907. Oklahoma led all the States in production, with a total of 45,798,765 bbl., an increase of 5.23% over 1907; Cali-

fornia was a close second, with 44,854,737 bbl., an increase of 12.85%; but Illinois gained the greatest percentage, rising from 24,281,973 bbl. in 1907 to 33,685,106 in 1908, a gain of 38.72%. Colorado, Louisiana, Michigan, Missouri, Utah, Wyoming, and West Virginia also showed gains in production. The losses were in Indiana, Kansas, Ohio, Texas, Pennsylvania, New York, Kentucky, and Tennessee. The average price of petroleum for the entire country in 1908 remained identical with that in 1907, but there were considerable variations in individual States.

Jonathon Bourne, Jr., of Oregon, has introduced in the Senate a bill providing for the disposal of lands chiefly valuable for oil. The bill provides that any citizen or association or corporation may file a declaration that he or they intend to explore for and develop the oil in a tract of land not exceeding 160 acres. No entry shall thereafter be received for this land for two years unless the claim has been abandoned or cancelled. The provision is contained in the bill that if there are any veins or lodes of quartz or other rock or placer-bearing gold, silver, or other valuable deposits known to exist at the date of filing application for patent, title shall not pass under this act, but such minerals are expressly reserved and shall be subject to location and entry by any qualified person under the provisions of the United States mining laws.

GOLDFIELD, NEVADA.

Consolidated Refinery.—Florence.—Goldfield Daisy —Fraction.

A. H. Howe, of the Consolidated Mines Co., denies a purported interview with him lately published in New York, in which he was quoted as saying that the high ore extraction in March was the result of a series of mistakes in sending to the mills ore the value of which had not been ascertained by sampling. It is explained that in opening up the Hampton stope in March, ore was found with which no experiments had been conducted. This ore averaged \$190 per ton, but the mill-heads were kept down to about \$60 by mixing in ore of lower grade. The tellurium in this orebody renders it refractory to milling, and a large portion has been shipped to the smelters. The Consolidated company's refinery is now outputting bullion bars at the rate of over \$17,600 daily, and the mill-heads are being maintained at \$35 per ton.

The extent of the latest find in the Engineer's vein of the Florence mine has not yet been determined, but the ore is exceedingly rich, carrying free gold and gray copper, in jasper. Some of the assays have run over \$60,000 per ton. It is the intention of the Florence managers to explore the vein at greater depth than the present deepest point, 500 ft., upon the completion of the main shaft. Within three weeks the new equipment will have been installed in the Florence mill, which will then have a capacity of 160 tons daily. During May the Florence produced 3353 tons of ore, with a gold recovery of \$33,500. The Goldfield Daisy is now being worked on a profitable basis, and it is the intention to increase the shipments of smelting ore. In a lease on the Daisy and adjoining the Great Bend a small vein of rich ore has been exposed at a depth of 250 ft. In sinking the Victor shaft of the C. O. D. Consolidated the vein has been cut below the 400-ft. level, and production will shortly be resumed. The ore carries a high percentage of gray copper in addition to gold. The Combination Fraction mine is maintaining its regular output of 80 tons daily, and the mill is said to be making a satisfactory recovery. Two bars of bullion from this mill were sent out recently, valued at \$16,000. On the Goldfield Merger Mines Co.'s claims three leases are in good ore. Driving will be resumed at 200-ft. depth on the lease of the Combined M. & L. Co. The Kansas City Velvet has a good vein of rich ore, which has shown some improvement with recent development.

In the eastern part of the district sinking has been resumed and extensive work outlined on the Nancy Donaldson. A hoist and head-frame have been installed and some good ore found in the vein at a depth of 100 ft. This group of claims is on the Red Mountain mineral belt, and ore assaying over \$3000 per ton was found near the surface. No

deep work has been done at this point. It is announced that work will be resumed on the claims of the Diamondfield Red Mountain Co., where there are large deposits of mill ore exposed. Near the town of Diamondfield work is now in progress on the Goldfield Eureka, the Goldfield Apex group, and on the Goldfield Retter. On the Laguna, lessees are developing at a depth of 718 ft. from the Hazel Goldfield shaft. Another deep shaft is to be sunk on the Poleverde claim, owned jointly by the Consolidated and Jumbo Extension companies.

BUTTE, MONTANA.

Boston & Montana — Badger State. — Butte Coalition. — Colorado. — Gilsonite Discoveries.

The signs of the times on the Butte hill point to prosperity. From the financial crash of two years ago, when all work connected with the production of copper was materially curtailed, the mining activity of the district is slowly but surely recovering. One of the most encouraging facts given out by J. C. Adams, manager of the Boston & Montana properties, is that the mines under his control are now shipping more ore than at any previous time in the history of the company. Whereas a short time ago the monthly output was only 110,000 tons, it now is 140,000 tons. Three thousand five hundred tons daily are being shipped to the Boston & Montana smelter at Great Falls for treatment, and approximately 20,000 tons per month are being shipped to the Washoe smelter at Anaconda. With the enlargement of the Great Falls plant which is to be made in the near future, it is probable that the capacity of the plant will be so increased that the entire tonnage from the B. & M. properties here may be handled there. Work at the Badger State mine has been started again under the most favorable auspices, and the shaft, which is already 1200 ft. deep, will be sunk to 1800 or 2000 ft. The head-frame which formerly was at the Minnie Healy has been removed to the Badger State and erected, and the flat-rope, double-reel engine formerly at the Mountain View mine has been installed. This gives the Badger State excellent equipment, and work will be pushed as rapidly as possible. The Tramway property of the Butte Coalition Co. is now hoisting 750 tons per day, and the ore is running from 3 to 5% in copper. The Tramway has one of the finest surface plants in the country, electricity being utilized extensively and all of the most modern labor-saving devices being in evidence. The engine is of 20 hp. The entire plant was erected at a cost of \$360,000. The Minnie Healy is being operated through the Tramway shaft, the 1300, the 1400, and the 1500-ft. levels having been already opened up.

At the Colorado mine of the Davis-Daly Estates Copper Co., where the shaft is being sunk from the 1485 to the 2000-ft. level, 5 ft. of 5% copper ore has been found. It is also stated that an excellent and apparently extensive body of ore has been cut into on one of the lower levels of the property. The Colorado is now employing 100 men and is hoisting about 100 tons of ore per day. If the good fortune of this company continues it will be able to open the basin concentrator before the time set, some time during the early winter. The surface plant has been entirely changed, and consists of a 60-ton head-frame and a 22-drill Nordberg air compressor. The sinking and much of the development is being done by contract, and some record work has been made in the district during the past few months. The property is situated in the heart of the city, and the ore body is somewhat short of surface ground. A retaining wall is being built to remedy this feature in a measure. It is stated that the gold in the ore being sent to the Washoe smelter at Anaconda is sufficient to cover the cost of their extraction.

A large deposit of gilsonite has been discovered on Redstone creek, in Dawson county, Montana, by J. B. Holloway. Mr. Holloway and two associates have secured control of all property contiguous to the new find, and have already been offered a large sum for their interest. Gilsonite is only found in commercial quantities in the United States in the Uinta basin.

SALT LAKE, UTAH.

Fink Smelter. — Ohio Copper. — Mascotte Tunnel. — Knight Mines Sale. — Tintic Production.

The test that was to have been made with blister copper in the Fink furnaces was postponed by reason of a break in the temporary blowers that have been installed. During the week arrangements will be made for this demonstration in the presence of Samuel Newhouse, E. A. Wall, and some metallurgists. Several successful runs have been made on Boston Con. concentrate, and in converting a matte that carries from 65 to 80% copper. E. P. Jennings and Frederick W. Scofield, both metallurgists of high standing, have witnessed demonstrations of the Fink furnaces in the interest of New York and European capitalists. They have no hesitancy in saying that the Fink method will be successful in making copper matte at a low cost. A permanent smelter, constructed on the Fink lines, with a few mechanical alterations, is now being considered by Mr. Newhouse and some capitalists of this city and New York. This plan may not be carried to a successful conclusion for several months, as it is the desire of those who are to become financially interested that Mr. Fink first make some further experiments with his blower. It has been Mr. Fink's idea at all times to smelt the ores without the assistance of any foreign material, and in a measure he has unquestionably been successful. It is now proposed that tests be made with lead ores from the mines at Alta and other districts, using fluxes.

Ohio Copper will have its mill in commission some time in August. This is the report given out by Frank Jones, who has charge of the construction work. The first unit will have a capacity of 500 tons per day, while the entire plant will be capable of treating about 2500 tons. It differs from both the Utah Copper and the Boston Con. plants, having rolls for crushing, in place of Chilean mills and Nissen stamps. The mill will be under the supervision of William Kidney, of the Heinze staff at Butte. The Mascotte tunnel has been driven a distance of 13,900 ft. into the mountain, and is within 100 ft. of the Ohio Copper and Utah Copper end-lines. At a point 13,500 ft. from the portals of this tunnel an incline is used to carry supplies and men to the various workings. The principal work is now being done on the third, fifth, and seventh levels. A raise is being made from the tunnel level along the ore-shoot. This will connect with the various levels. A chute will be put in and the ore dropped to the tunnel to be hauled to the mill. The mine is opened up into ore blocks 100 ft. square. It is estimated that there is enough ore now in sight to last 20 years, and the sulphide zone on the hanging-wall side of the mountain has not been explored.

The Mascotte tunnel is to be the main thoroughfare for transporting the ores from Bingham mines. It is owned by F. Augustus Heinze, and is one of his principal assets in Utah. He will extend it into the Utah Copper and Boston Con. territory. It will cut the former at a depth of 800 ft. below the present steam-shovel workings, and the Boston Con. at a depth of 1600 ft. From these properties it is planned to extend the tunnel 18,000 ft. through West Mountain range to the ore-bins of the International Smelting Co. plant on the opposite side of the range, in Pine canyon. Branch tunnels under the various mines will make possible a great saving in transportation charges. It is believed that this will be accomplished within a couple of years.

Since Jesse Knight has been in New York a number of statements have been given out relative to the proposed sale of the Colorado and Iron Blossom mines and the Tintic Smelting Co., all of which Mr. Knight controls. From one who is interested in the deal it is learned that the sale will involve something like \$6,000,000. The three large smelting companies are mentioned as the probable purchasers. Colorado is to be put in at \$2,500,000, Iron Blossom at \$2,000,000, Tintic Smelting Co. at \$1,000,000, and the Tintic railroad to the mines at \$380,000. The mines are silver-lead producers, each paying monthly dividends of \$80,000. The smelter has 4 lead and 1 copper furnaces, of a capacity of 225 tons each. Should Mr. Knight dispose of these holdings, it does

not mean that he would retire from the mining business. He has a controlling interest in a score of other properties that are being developed, but the Colorado and Iron Blossom are his principal producers. Tintic mines are now producing about 6000 tons of ore each week. Almost half of this amount is being mined in the Centennial-Eureka, owned by the United States Smelting Co. This mine has been one of the largest producers in the State for a number of years. It has copper-silver-lead ore, and at a depth of 2260 ft. driving is now being done both ways in ore. Operations have been little hindered by water, the pumps handling the water easily at this great depth.

JUNEAU, ALASKA.

Mining Resumed.—Auk Bay Discoveries.—Alaska Treadwell.—Eagle River.

The mines of Silver Bow basin have resumed operations for the summer season. The great depth of snow and the lateness of the spring season will make this year's run short. The Perseverance mill is dropping 100 stamps, and the company is employing about 150 men. The Alaska Juneau mine has resumed operations under the superintendence of L. K. Kennedy, and a successful season is anticipated. The Ebner mine is still idle, pending the closing of some important deal. There has been considerable excitement in this district over the discovery of some good looking prospects at Auk bay, about 12 miles northwest of Juneau. Both placer and lode claims have been located, and while nothing has been proved as yet, the outlook is good. It is reported that the ore is similar to that of Silver Bow basin, and exists chiefly as quartz stringers in schist. Every launch and rowboat in Juneau has been pressed into the service of the prospectors and all the ground for miles around has been located.

During the year ending May 15 the mills of the Alaska Treadwell Gold Mining Co. crushed 768,628 tons of ore with an average assay value of \$2.57. The average number of machine-drills at work in the mine during the year was 39, drilling 28½ ft. per shift and breaking one ton for every 0.96 ft. drilled. In the 240 mill the 900-lb. stamps crushed an average of 4.79 tons per 24 hours per stamp. One pound of steel in the shoes crushed 3.06 tons of ore, and one pound of iron in the dies crushed 4.79 tons. In the 300 mill the 1050-lb. stamps crushed an average of 5.34 tons per stamp per 24 hours. One pound of steel in the shoes crushed 2.40 tons of ore, and one pound iron in the dies crushed 5.61 tons. It has been decided to install a central power plant at Treadwell to generate electric power for the lighting, pumping, and other purposes where its application will be more economical than that now in use. The first installment of the plant will consist of two Westinghouse-Parsons steam turbines, direct connected to two 750-kw. 1000 K. P. A. generator units. Work on the new dam at the head of Bullion creek will be pushed this season, and it is hoped that its full capacity will be available when the water begins to be short this fall.

The Eagle River Gold Mining Co., managed by B. L. Thane, is employing a force of 45 men and operating a 20-stamp mill on Eagle river, 25 miles northerly from Juneau. The mine and mill are seven miles from the company's wharf on Lynn canal, a surface tramway of that length serving as a means of transportation. The mine is on a belt of ore that strikes northeasterly, on a contact of granite on one side, and slate and schist on the other. Within a belt that ranges from 50 to 100 ft. wide there are two systems of ore-shoots, one adjacent to a limestone and slate hanging wall, and the other along a foot-wall of altered diorite. The black slate between contains several ore-shoots. These are 40 to 100 ft. long, and 2 to 20 ft. wide, and pitch northeasterly. The gangue is quartz, containing free gold, arsenical pyrite, stibnite, galena, zinc-blende, pyrrhotite, chalcopyrite, and bornite. The property is developed through a vertical depth of 1000 ft. by 10 levels, some of which are cross-cuts and others are drifts on the ore. All levels are connected by raises, the lowest level, 1400 ft. long, being connected with a 2000-ft. aerial tram

way, over which the ore is sent to the mill. All levels, drifts, cross-cuts, and raises aggregate 17,000 ft. of work. The mill, having twenty 1000-lb. stamps and six Wilfley tables, has been operating since April 1904, and during that period about 70,000 tons of ore have been milled, running, approximately, \$10 per ton. About 90% of the total extraction was made on the amalgamating plates, the concentrate product running \$50 to \$100 per ton in gold, silver, and lead. Eagle river is a glacial stream that heads in Herbert and Eagle glaciers, flowing down Eagle valley into Lynn canal. The government wagon-road and trail, which it is proposed to build from Juneau to Eagle river, will aid prospectors and explorers in their efforts to make locations and develop claims on the mineralized belt extending along the coast range parallel to Lynn canal. This road-building is to begin July 1. Its further extension from Eagle river to Berners' bay is a part of the plan outlined. From Eagle river north to Berners' bay, a distance of 20 miles, many mineral locations have been made.

BRITISH COLUMBIA.

Eva Mine.—Slocan Zinc.—Silver to Hong Kong.—Copper Costs.—New Dominion Re-organization.—Western Canada Power.

The Eva mine at Camborne has been bonded by American capitalists. This property is well equipped with machinery, there being a modern air-compressor and power-plant on the ground, as well as a 10-stamp mill and concentrator. There is a large tonnage of low-grade gold ore in the mine; it being possible on some of the large surface lodes to work on the 'glory-hole' plan. The mill was put in about five years ago and worked steadily up to a year ago, when it was decided to sell the property. During the period that the mill was in operation about \$250,000 was produced in gold bricks. That the Slocan zinc district is a factor in the fight now being waged at Washington is evinced by the presence here of J. A. Ede, of the Illinois Zinc Co., who is studying the local situation. T. F. Noon, general manager for the company named, has been in Washington protesting against the proposed zinc tariff. Another one of the regular shipments of silver that the Consolidated smelter at Trail has been making to banking institutions at Hong Kong was sent on its way last week. It comprised 54 bars of the white metal 0.999 fine and was valued at about \$55,000. The silver is used for coinage in the Orient. The Trail refinery is also furnishing the Dominion Mint with metal. Work has not yet been resumed at the mines of the International Coal & Coke Co., Coleman, and as a consequence the British Columbia Copper Co. is still without a supply of coke for its smelter. The fifth annual report of the International company shows that the net profits for the past fiscal year were \$284,210. The company recently sold 200,000 shares of its treasury stock, the proceeds of which will go toward paying off the bonded indebtedness. The British Columbia Copper Co. has been mining, smelting, and converting its copper at a very low figure during the last year, but a record low cost price was made during the last month of operation when the product of the plant was landed in New York at 7.96c. per pound. The lowest cost that had been reported prior to the above was 10c. per pound. The British Columbia Copper and Granby companies can now make copper at as low a cost as most copper mines on the continent. They have installed labor-saving devices in and around both mine and smelter. The orebodies of this district are big, so that large quantities can be broken at once.

It is expected that the property which the Hayden syndicate bought in at Vancouver will now be turned over to the New Dominion Copper Co. and securities issued, as was stated at the outset of the re-organization proceedings; that is, that the new company will issue \$500,000 in 6%, ten-year income bonds, and 250,000 shares of common stock, par value \$5 per share, the present bondholders to be paid in stock to the amount that the company is found indebted to them, while the bonds will be disposed of to the old shareholders and others in order to raise a working fund. Word comes from London that financial arrangements have been completed for the carrying out of a big plan of development

at the Le Roi mine, Rössland. The plan is to thoroughly prospect the depths of the mine with diamond-drill from the 1650 to the 2650-ft. level.

Last week the interests of the Stave Lake Power Co., near Vancouver, were absorbed by a new \$5,000,000 company, the Western Canada Power Co., which expects within 18 months to be able to deliver 30,000 electrical horse-power to this district. At present there are about 60 men employed constructing the dam and plant, but a much larger force will be put to work almost immediately in order to hurry the work. Great progress is being made at the group of claims owned by the Portland Canal Mining Co. near Stewart. Two of the tunnels are being driven and raises run from them, while a new tunnel has been started. Towers are being built for the aerial tramway.

DENVER, COLORADO.

Electric Power.—Clear Creek. — Portland Mill. — Petroleum.

The Colorado & Southern railroad is preparing to electrify its South Park, Clear Creek, and other mountain lines, and part of its Denver terminals. John F. Stevens, late vice-president of the New York, New Haven & Hartford, is expected here soon to make an official report on the project. Plans have about been completed for the construction of a plant at Mill Gulch, on the South Platte. The South Platte Power Co. is the name of the corporation that is preparing to construct the plant. H. C. Jahl, an electrical engineer from the East, is in charge of the power project. The plant is expected to generate 20,000 hp., and will cost approximately a million dollars.

In Clear Creek county the usual summer activity has begun. A contract was awarded this week by the Mammoth M. & M. Co. for the sinking of the shaft on the Mammoth vein an additional 50 ft. This will make the total depth a trifle over 200 ft. This property lies in East Argentine, and from the present workings high-grade ore has been mined. Previous to the suspension of work last fall the shoot was lost, but it is planned to start driving east and west in an endeavor to discover the same. The Humming Bird M. & M. Co. has purchased the Big Chief lode, situated on Lexington mountain. Work has been put under way in the repair of the old workings, and everything will shortly be in condition for the extraction of a large body of ore that is now exposed. Richard Staley of Idaho Springs is manager. Moonan & Oxley have taken a lease upon a block of ground on the 1000-ft. level of the Lamartine mine.

At Cripple Creek work will shortly commence on the construction of the Portland G. M. Co.'s mill. The site selected is midway between No. 2 and No. 3 shafts, on the northeast slope of Battle mountain. At Colorado Springs good success is reported in raising money for the drainage tunnel. It is said that the subscriptions now made assure the completion of the work.

Petroleum is attracting considerable attention now in Colorado. T. G. Brice, superintendent for the Lime Creek Oil Co., operating in the San Juan county, Utah, field, reports considerable activity in that section. The oilfield is now beyond the prospective stage, and heavy rigs are being installed and every preparation being made to market the oil now ready to ship. A pipe-line has been projected and will be laid to the railroad, a distance of about 75 miles, and plans are also drawn for a local refinery. The Lime Creek Oil Co. owns 2080 acres of land in the heart of the proved oil territory, and has two good wells drilled. One of these is in the first sand and showed oil at a depth of 200 ft. The second well was sunk into the second sand, and now has 400 ft. of oil standing in the casing. This well was a gusher, and had to be capped. Cripple Creek men are interested in the new field, and the Fisher Oil & Land Co. was incorporated in Denver this week. The Fisher company owns 320 acres, and the incorporators and officers of the company are D. C. Williams, Charles Fisher, and W. L. Turner. Petroleum has been several times reported from the south eastern part of Colorado, also, and it is possible that an oil field exists there. It is expected that R. D. George, State Geologist, will make an examination this season.

LOS ANGELES.

Independent Pipe Line.—Coalinga Drilling.

The most important recent development in the oil situation is the completion of the organization of the independent producers' pipe-line company which took place in Bakersfield Tuesday, June 15. Such a project has been under consideration for a long time, and has gradually taken definite form since the independent producers have found an ally in the Union Oil Co. The rumor that the Union is backing the independents is authenticated from a reliable source and is also shown by an examination of the personnel of the officers of the new pipe-line company. These are as follows: president, L. P. St. Clair, president Independent Producers' Agency; vice-president, S. W. Morsehead, president Coalinga Independent Producers' Agency; secretary, Giles Kellogg, secretary Union Oil Co. of California; treasurer, H. H. Welch, treasurer of the Independent Producers' Agency. It is impossible to obtain reliable information at present as to who are the financial backers, but it is surmised that they are among the capitalists who have backed the Union, American Petroleum, and other similar companies, and who are believed to be independent of Standard, Associated Oil, and Southern Pacific influence. The capital stock of the new company is \$3,500,000. The intention is to build an 8-in. pipe-line with a minimum capacity of 10,000 bbl. per day, from a point in the Antelope valley, 14 miles south of Dudley, 60 miles to Port Harford, San Luis Obispo county, by way of Polonio Pass, Shandon, Santa Margarita, and San Luis Obispo. Branch 8-in. lines will connect the Antelope Valley station with Coalinga, 40 miles to the northwest, and the McKittrick, Midway, and Sunset districts, 36, 55, and 61 miles, respectively, to the southeast. A branch line 40 miles long will connect the Kern River field with McKittrick. Should the one 8-in. line connecting Antelope valley and Port Harford be insufficient to transport the oil from the feeders, another 8-in. line will be put in along the same right-of-way. The completion of this pipe-line system will indeed make the independent producers what their name signifies. It will mean that the bugaboo of over production, which has been stalking about of late owing to the inability of the marketing and transporting companies to properly handle the supply from some of the San Joaquin Valley fields, will be driven off for many years to come, if not forever. With the steadily growing market and limited productive area, the condition of over production ought never to be anything more than a temporary and local menace, if transportation facilities are at all adequate.

Wildcatting in the north end of the East Side field has shown that the productive territory extends no farther than the middle of Sec. 2, T. 19 S., R. 15 E. Graham No. 3 in Sec. 2 and Tavern No. 1 in the S. W. $\frac{1}{4}$ of Sec. 38, T. 18 S., R. 15 E., and Peerless Consolidated in the S. E. $\frac{1}{4}$ of Sec. 28, of the same township, have been abandoned after drilling into and through the oil-sands and finding them devoid of commercial quantities of oil. Attention is now centered on the wells in sections 22 and 26, T. 21 S., R. 21 E., on Jacalitos creek. These wells are drilling for the sand in the Jacalitos anticline, which according to the U. S. Geological Survey report, lies at about 3600 ft. below the surface near the axis of the fold in the creek bed. It is rumored that the El Cerrito well, in Sec. 14, T. 23 S., R. 17 E., is about to be abandoned, no indications of petroleum having been struck in the 3300 or more feet of sand and shale through which this well has been drilled. It is reported that Golden Crest No. 1, in the N. W. $\frac{1}{4}$ of Sec. 12, T. 22 S., R. 15 E., has struck traces of oil in thin sand in dark-colored shale. This well is now down 1940 ft. Should any of the wells now drilling south of Waltham creek be successful, the proved productive territory in the Coalinga district will be quite materially increased.

On May 1 there were over 440 producing wells in the Coalinga field and 125 drilling. The American Petroleum wells recently brought in indicate that the production increases with the depth. To what limits this holds true, it will be interesting to note as development progresses.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Lode-line in a mining claim is theoretically the central line or longitudinal axis. The law, however, has not been construed so as to make it essential that the actual should coincide with the hypothetical lode-line. It contemplates that a locator shall lay out his lines so as to conform generally to the course of the vein, and cover it substantially.

Blau gas is a new form of illuminant introduced into Germany. It is a liquefied gas, which is sold in tanks of 22 lb., costing \$2.90. This quantity will supply a 50-candle-power burner 480 hours. The liquid is drawn into cylinders or globes of special lamps, where it becomes re-gasified. It is said to be free from carbon monoxide, and is non-poisonous.

Jigging is always desirable as a means of concentration when the heavy mineral can be broken clean from gangue by relatively coarse crushing. In many cases the percentage of metalliferous mineral saved can be raised by a preliminary jigging before fine-grinding. Comminution of ores, such as is requisite in preparing them for concentration on Wilfleys and slime concentrators, always renders close-saving more difficult.

Tungsten deposits are usually irregular in their content of tungstic acid (WO_3), and are also liable to be rather superficial. The speculative value of a tungsten deposit is therefore exceedingly small. A prudent purchaser will not pay for more than he can calculate to be available in the mine, as shown by the present development. The price of tungstic acid in ore or concentrate exceeding 50% is about \$5 per unit at Eastern points of demand.

Cutter Cove, perhaps the best developed copper mine in the Territory of Magallanes (Magellan), is situated on the west coast of Brunswick peninsula, near the north entrance to Gerome channel (canal Jerónima), and close to Otway sea. It is about 120 miles from Punta Arenas, Chile. The veins vary from 4 to 7 metres wide, and shipments of sorted ore have yielded an average of 7% copper, with about 7 oz. silver per ton. The Cutter Cove Copper Mining Co. is installing a smelter, and a concentrator to clean the low-grade ore.

Opinion concerning origin of the gold in the 'banket' of the Transvaal varies among geologists. Some hold that the deposits are veins in the ordinary sense, the tilted conglomerates having merely formed permeable zones through which the mineralizing solutions, induced by the associated volcanic dikes, had circulated; others affirm that they represent ancient placers, an argument which weakens in the face of the crystalline character of much of the gold. A third hypothesis is that of solution of the original gold in the conglomerates, and its deposition by chemical reaction, which finds support in the crys-

talline character of the metal, and its association with secondary pyrite crystals and concretions. The 'banket' is not of uniform grade; the variations in gold content are often sudden.

Sea-water affects portland cement by dissolving the lime and depositing sulpho-aluminate of lime, which expands and causes disruption. Concrete will withstand sea-water for five or six years, but will break down rapidly from that time forward. Cement for such situations should be mixed with fresh water, and coarse sand, from which the fine has been screened, should be used. The cement should not be 'over-limed' nor should it contain magnesia. The boiling test is of great utility in proving up the quality of cement for use in salt-water.

Tin in Alaska is found in the western part of Seward Peninsula, about 100 miles northwest of Nome. The localities are known as Ear Mountain, Buck Creek, Cape Mountain, and Lost River. Placer tin is found, but important veins also exist. The veins are associated with limestones and quartz porphyry dikes, the latter cutting through granite. The tin was evidently introduced by gaseous emanations, and most of the characteristic mineral associates of tin are present, together with new minerals, which have caused misconceptions to arise in prospecting.

Explosives stored in caves, tunnels, or in mines are subject to deterioration from moisture. The same is likely to occur when storage magazines are made of stone or brick. The Austrian law requires that magazines be made of wood, with a double sheathing, leaving a hollow space between. The material is required to be extremely light, and only small nails may be used. Such a magazine should be isolated from all sources of conflagration. It is also a most important protection to surround a magazine with an earthen wall as high as explosive is stored. This deflects upward the violence of an explosion and effectually protects surrounding structures.

Copper smelting on the converter principle was tried at East Butte, Montana, and failed. This was the Baggaley process. The Knudsen process, in Norway, is said to yield good results, but it is manifestly limited to a narrow range of ores, and the costs in America would undoubtedly equal those of pyritic smelting. The Fink process is not yet a demonstrated success. The merit in the Fink idea lies in turning over the concentrate by the revolution of the barrel-shaped converter, so as to expose the material to the action of the flame; in short, it means smelting with continuous rabbling. Perfection of detail has not yet been attained. The combination of conversion with this initial melting is of problematic value. Unless conversion, once started, can carry the matte up to 'blister copper', ready for the refinery, it has no practical utility. There is a field for such an appliance in the handling of concentrate, but converter smelting of ores has no reason for existence. If an ore lend itself to simple pyritic smelting, the blast-furnace possesses manifest advantages for inexpensive treatment.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Panama Canal.

The Editor:

Sir—Absence prevented my seeing your issue of April 24 until a few days ago. Hence my reply to its collection of attacks upon myself is belated. A word of explanation to your readers. In your number of December 19 last you spoke much in derogation of several prominent engineers by comparing their ability unfavorably with that of Lewis M. Haupt. Being, as I stated, familiar with Mr. Haupt's engineering, I undertook, in a personal letter, to try to set you straight. I did not intend to attack him publicly. I did intend to criticise him as an engineer before one editor, because I consider his engineering to be a menace to public welfare. He has already induced Congress to waste half a million of dollars at Aransas Pass, Texas, and ruined the port. You presumed to publish my personal letter in your issue of March 27, thus giving Mr. Haupt's friends the right to think I had gone out of my way to make an uncalled-for attack. For this, you, and not I, should apologize to them. I stand for every word of my letter, which I meant just as I wrote it, without, as your correspondent, H. M. Chance, insinuates, using any "cunningly worded innuendoes." F. Lynwood Garrison criticises me for "claiming to belong to the mining engineering profession," and he "gleans" from my reports a very unfavorable view as to my ability. Mr. Chance would like to have the Mining & Metallurgical Society take up my case as practising a profession for which I was not trained. These charges have no bearing upon the competence of Mr. Haupt to improve harbors, but if I let them pass, your readers will think them true. If I reply to them, I will be using your columns for free professional advertising. As you, Mr. Editor, are responsible for the matter, I am constrained to adopt the latter course and reply, even though it involves too much of the 'perpendicular pronoun'.

The curriculum at West Point covers more geology and mineralogy than many mining engineers ever find occasion to use, while mining in one material sense is an important branch of military engineering. It also happens that I have spent a good part of the last seventeen years studying the origin of precious metal deposits and allied subjects, four years of the time under very favorable circumstances, as I spent a large part of that time in the mining camps of California, covering nearly all of them, on a duty that threw me into direct contact with mines and miners, and I made the best possible use of these and all other opportunities. I will not impose upon your space to recite all these, or the extensive study I have made of the literature of the subject. I have also had a working or supervising interest in several mines. And further, in addition to "commending your mining geology," I have even had the "impertinence and

audacity" to prepare part of the materials for a book on the subject of the indications, favorable and unfavorable, to persistence in depth of precious metal deposits. This subject is at present covered only on the one hand by elaborate geological descriptions, of most of which no one can yet make practical application, and on the other by scattered observations of so-called 'practical miners'. However, I have not attempted to cover the entire field of engineering, mining or otherwise. Precious metal deposits and hydraulics are not too large for one engineer to cover, and I believe I can be useful in both of these. I have made quite a number of reports on mining properties, in which I have covered the features I believe I understand. Those who have employed me, I have reason to believe, have done so with the thought that I would tell the truth as I saw it and not 'sell them out' in any way. They have all been satisfied with my work. I am not acquainted with Mr. Garrison or Mr. Chance, and cannot, therefore, express an opinion as to whether the same is true of all their clients. Mr. Garrison is far afield in his rather dark suggestions as to why I resigned from the army. The facts are that I was placed in a position where I either had to quit the army or quit the fight against the corrupt gang of grafters now governing Philadelphia. I chose the former, which choice was made possible by the public-spirited generosity of the late Thomas B. Wanamaker. After resigning, I did my duty as best I could. Had the former mayor, John Weaver, had the character and courage to do his, the tale would have been different, and Messrs. Garrison and Chance would not be getting excited at my "impertinent" intrusion into their chosen field.

As to my friend, Mr. Trautwine, I can only murmur, "Et tu Brute," and say that if there is nothing in my letter derogatory to Mr. Haupt, I failed to make my meaning clear. And now that I have explained that my letter was not written for publication, I trust that Mr. Trautwine will fully absolve me from "seeking applause exclusively for my side of the discussion" by asking an editor to inform himself by reading both sides of it.

However, the subject is too extensive to cover here, and, applause or no applause, I will again commend anyone interested to read the discussion and the original paper, which are to be found in the Transactions of the American Society of Civil Engineers, International Congress, St. Louis, 1904, beginning with Paper 14.

For the benefit of your readers I will give a brief resumé of Mr. Haupt's harbor theories and practices. In 1887 he published a paper on 'Ocean Bars', for which he received a medal from the American Philosophical Society. The above-mentioned discussion shows, I think, conclusively, that every point he made in his paper was wrong, except one, and that was unimportant. The fundamental fact on which he based his theory is shown by the charts to be an error. Worse than that, it was a false statement almost impossible to explain away. It was that every harbor entrance from Jekyl island to Cape Florida was flexed to the north, whereas every one of them except one unchangeable one, was flexed the other way. He tried the same year to get his theories and

plans adopted by the Army Engineers, but they correctly and properly rejected them. Since that date he has lost no opportunity, on every possible occasion, in public and in private, to complain of this alleged unfair treatment. His complaints have been unjust, unfair, and in every way calculated to impress an unprejudiced observer with the fact that the mind that produced them was either wicked in trying to incite prejudice against a most honorable body of men, or else incapable of seeing things with a just balance. Eventually, he got a chance with a private company to try his theories at Aransas Pass, Texas, and though in many writings since he has pretended that this work was in accord with his paper and plans rejected in 1887, there is not one single plan or principle common to the two things. This is perhaps unfortunate, because his present plans have ruined the port, and his 1887 plans could have done no worse. Although officers of the Corps of Engineers have repeatedly pointed out that Mr. Haupt's fantastic jetty at Aransas Pass must be connected with the shore, he has always, by pleading with Congress, been able to prevent this, and now, as was to be expected, the currents have recently dug a deep gorge between the jetty and the shore, resulting in the utter ruin of the port for many years to come. During the discussions that have obtained concerning this work, some things have occurred that show to what extremes a man "who stands up so straight that he leans over backward" will go to defend an erroneous theory. The principal function of Mr. Haupt's Aransas jetty was to keep the drifting sands out of the channel by catching them and storing them at its back before they got into the channel.

In one paper he claimed that the jetty had done this to the extent of 400,000 cu. yd. When it was shown that instead of that amount having been stored behind the jetty, the storage place has lost over two million yards, he explained that the 400,000 yards had gone through some little gaps in the jetty and been later scoured out by the currents—a vastly different matter, and a very poor solution of the problem. This claim was about as honest as to claim that a watchman had kept the burglar out of the house by letting him in at the parlor door and some hours later ejecting him from the kitchen window. On this one episode I take direct issue with Mr. Haupt's defenders as to his candor and trustworthiness.

In his recent reply to my letter under discussion, Mr. Haupt denies my statement on two points. One is the Canal Commission episode. I was not there. I told the tale as it was told to me, with the extra pair of eyes and all. Circumstances beyond my control make it hardly proper for me to name my authority publicly, just now. Had you treated my letter as personal, I could have named him to you. And I can hardly call successfully on members of the Commission, but Mr. Haupt can. They would not think it improper to defend a fellow member, and if he will get one of them to say my statement is in error in any essential, I will name my authority, for I repeated the story accurately, and my informant is not a man who "skirmishes with the truth." Mr. Haupt also flatly denies my statement as to the organization of his

Reaction Jetty Company and subordinate companies. For reply, I quote the following from his own pamphlet on the subject, which he furnished to the Board on Improving the Mouth of the Columbia River: "The Reaction Jetty Company, authorized capital \$1,000,000, 200,000 shares, full paid and non-assessable; incorporated by the State of Delaware, 1902; Lewis M. Haupt, C.E., president; Benj. C. Potts, secretary; principal office, Arcade building, Philadelphia; local agent, The Delaware Trust Company, Wilmington, Del. Proposed method of operating: To carry on the work for which proposals have been submitted to the Secretary of War, under the present appropriations, and where the choice of plans has been left to his discretion, local subsidiary companies are being organized, of representative citizens who desire to avail themselves of the immediate results and deeper channels assured by the introduction of this system, and arrangements will be made to employ local plants and sub-contractors for the equipment and conduct of the work, which involves no risk beyond that of constructing ordinary rock breakwaters. As payments will be based on work in place, under the usual provisions of inspection and monthly returns, a large amount of working capital will not be required at any one locality, and as a consideration for the contract, it is proposed not to charge the Government any royalties for the use of the method, provided the work be given to this company at unit prices which are mutually satisfactory, accompanied by the usual guarantees."

If that does not establish the truth of my statement, I do not understand the English language. And if ever a plan was proposed calculated to introduce the horrors of municipal graft like that of Philadelphia into our now honestly and competently conducted river and harbor works, this of Haupt's Reaction Jetty Co. was surely the worst.

CASSIUS E. GILLETTE.

Philadelphia, June 11.

[Right of rejoinder belongs to him who leads the debate. The matter at issue originally concerned the Panama Canal; it has passed now into mere miasm which it would be offensive to longer tolerate. Questions as to the personal attainments of Messrs. Haupt and Gillette may well rest on the fame each has attained. We fancy that all men have made errors; and that good reputations grow and persist because their successes overbalance their failures. The name and fame of Mr. Haupt as an engineer and as an honest man are so well known that he needs no defense; his reputation is international, and no one can damage it. The reputation Mr. Gillette has made as an indefatigable enemy of the grafter is also a matter of national knowledge, and the people owe him gratitude for his distinguished services in that direction. It is deep cause for regret that personal animosity should have developed in connection with this entirely unnecessary discussion. It would be pleasant to think that our superior men were also superior to letting their thunder be drawn by things which are non-essential. Our remarks which called forth this unfortunate tirade were not an exaltation of Mr. Haupt, as the correspondence might seem to

indicate; we merely referred, in passing, to the attitude of Mr. Haupt in subscribing to the report of the Canal Commission that recommended the Panama route, expressing regret, and hinting that he may have done it in deference to the conviction that it was 'either Panama or nothing'. At the moment when our editorial was published, the country was excited over supposed irregularities in relation to the Canal; the spread of adverse sentiment might have brought pressure to bear upon Congress to curtail appropriations. Such a course would have set back the Canal, perhaps for years. The keynote of the editorial, the patriotic theme to which it was written, was contained in our sentence, "Investigation is proper enough, but the digging must continue;" and again, "Let it be understood that an enterprise of this kind must be pushed unremittingly on an adequate scale, or what has already been done is as good as wasted." It was aside from the point, and in nowise helpful to the purpose we had in view, to raise a personal question. It is too late now to debate the choice of routes, and of little utility to probe the reasons that led to selecting Panama. It would have been welcome to have received from Mr. Gillette endorsement of our position on the great matter which inspired our comment at the time. We are not now called upon to pass on Mr. Gillette's geology nor Mr. Haupt's jetty theories: they may both be deplorable; but we do hope that they will both stand by their guns when it comes to defending the progress of the Isthmian ditch, which we need as a great commercial equalizer between the East and the West. If we misinterpreted Mr. Gillette's intention as to publishing his letter, it becomes our duty to apologize, both to him and to Mr. Haupt, for this muck-raking which has resulted. Our warrant lay in the last paragraph of Mr. Gillette's letter of March 11, omitted from the correspondence as published, which said, "Trusting that this letter and its references will not prove too extended to be of any use to you, I am, etc."—EDITOR.]

Rand Milling Practice.

The Editor:

Sir—Your usually well informed writers apparently have short memories on the subject of Rand metallurgical practice. In perusing your journal of May 22, under the title of 'Rand Milling Practice', your readers would gather that, to use your own expression, "the great mines are *coming* to the simple methods of fine grinding, agitation with cyanide solution, and filtering." Will you permit me to point out, that some of the great mines under our supervision at the Rand came to these methods as far back as 1905, in which year we installed, in the face of universal local opposition, "fine grinding (in tube-mills), agitation with cyanide solution, and filtering" at two mines: the plant on the New Goch mine, treating 700, and the Meyer and Charlton, 450 tons per day. We also advocated the disuse of the other 'innovation' to which you refer, namely the amalgamation process, saying in a paper read before the South African Association of Engineers in June 1906: "The writers have from time to time suggested the possibility of doing away with amalgama-

tion in the mill. The removal of the mill-plates would give easier access to the mortar-boxes, and would permit the placing of the mill work in the hands of trained fitters, whose duty it would be merely to see that the stamp-mill, as a machine, did its work of ore reduction effectively. The position of battery manager, with an attendant foreman, would then entirely disappear, and the whole of the gold treatment process would be under one supervision and separate entirely from the mill. * * * The feeling of the writers is certainly in the direction of doing away with the mill-plates entirely, and they would have no hesitation in equipping any mine on the Rand with this old-time method entirely eliminated." The 1600-lb. stamps, of which so much is heard lately, were introduced on the Rand by us in 1904. In that year we installed an experimental battery of 5 stamps of that weight, on the Meyer and Charlton mine, and secured an output of over 9 tons per stamp per day, through a 20-mesh.

In view of the foregoing facts, we read with considerable surprise in your columns that these 'innovations' are now being introduced on the Rand for the first time, and the credit given elsewhere. If we had not been subjected to the unfairest kind of criticism on the conception of these metallurgical features, and had the wildest doubts not been expressed as to the wisdom of our innovation, we could sit quietly and see the result of our work go unnoticed, but having had the persecution, and having had to more or less quietly endure it, we think we are fairly entitled to protest when our one-time detractors come forward with our schemes and claim credit for them as 'innovations'. We would refer you to our exhaustive paper, read before the South African Association of Engineers, in June 1906, for a complete defence and exposition of what was then called the 'Denny' metallurgy, and we assert without any fear of contradiction that all that has been done metallurgically on the Rand, of any consequence, since that time was forestalled by us several years ago, in the methods we were bold enough to adopt in the plants which were the subject of description in that paper.

G. A. DENNY.

Oaxaca, Mexico, June 1.

Fluorspar in 1908.—The total quantity of fluorspar marketed in the United States during the calendar year 1908, as reported to the U. S. Geological Survey, was 38,795 short tons, valued at \$225,998, a decrease from the figures for 1907 of 10,691 short tons in quantity and of \$61,354 in value. The marked decrease was due largely to the idleness of many of the open-hearth steel plants throughout the country, but in part to inactivity in the glass and enameling industries. Better conditions have prevailed in these industries during 1909, and the amount of orders booked by the fluorspar-producing companies indicates that the trade for 1909 will be more nearly normal. The bulk of the fluorspar was produced from the Illinois-Kentucky district, and the greater part of the spar was of the gravel variety, which is used as a flux in the basic open-hearth steel furnaces.

MINING ON PRINCE OF WALES ISLAND, ALASKA.

Written for the MINING AND SCIENTIFIC PRESS
By W. A. SCOTT.

Prince of Wales island is separated from the mainland by Clarence strait, which extends from Dixon's Entrance on the south to Sumner strait on the north. The island is 160 miles in length and has an average width of 40 miles, with a coast-line that is indented by inlets and sounds from opposite sides that almost meet. For instance, Chomondeley sound, on the east side, and Hetta inlet, on the west side, are separated from each other by a neck of land three miles wide, over which there is a Government portage. Kasaan bay, Port Johnson, Mora sound, and Big Harbor constitute other indentations of interest, because they are open waterways to the mineral deposits of the island. Mining and mine development are in progress in at least twelve different places, and it is estimated that there are 200 men at work on the island in connection with mining. Four mines are regular shippers of ore, and three or four others may become shippers later in the year. The Sulzer and Commercial, on Hetta inlet; the Mt. Andrew, It. and Goodro, on Kasaan bay; the Niblack, on Mora sound, are all copper mines, yielding some gold. The Dunton, on Kasaan bay, and the property of the Princeton Mining Co., at Dolomi, are considered gold mines; while the Noonshine, situated high on the mountain, overlooking Chomondeley sound, has opened bodies of ore containing galena, silver, and copper. In all cases observed the ore is exposed at the surface, and occurs in masses and lenses, rather than in veins and shoots. The better grades of the copper ore constitute chalcopryrite, as a rule, while in the lower-grade ore the copper is in some cases associated with magnetite, which occurs in great bodies. Two of the best developed properties visited have copper-iron ore on the contact of limestone and granite, and this seems characteristic of the island. The surface of the country is covered by spruce, hemlock, and cedar trees, with an undergrowth that includes everything from the fern and skunk cabbage to the mistletoe and devil club. Ketchikan is the principal supply centre, especially for the east side of the island, gasoline launches carrying passengers, mails, and supplies, making regular trips to various places. At Sulzer, on the west side, is the well stocked store of the Alaska Industrial Co., and Copper City and Klawack are also trading places.

The Sulzer mine, belonging to the Alaska Industrial Co., is managed by Chas. A. Sulzer, president of the company. Interested with him in the property is William Sulzer, congressman of New York. The mine is near the head of Hetta inlet, two miles from the beach, and 1500 to 2000 ft. higher than tide-water. At the beach is a wharf over deep water, ore-bunkers having 4000 tons storage capacity, the aerial tramway terminal, and a hydro-electric plant. The pipeline, which brings to bear a 330-ft. head of water on the Pelton wheel in the electric plant, is 3500 ft. long. The upper section consists of 800 ft. of 14-in. pipe, followed by 1900 ft. of 10-in., then 800 ft. of 8-in., all being wire-wound wooden stave pipe. The electric power thus generated is transmitted to the mine for

all power requirements. The tramway is of the Riblet type, is over 9000 ft. long, has 14 wooden towers, 22 half-ton buckets, having a carrying capacity of 12 tons per hour. The line makes an ascent of 1500 ft. from the bunkers to the upper terminal; toward the upper end there is one span of 2500 feet.

Operations began in a small way in 1902, and on a larger scale in 1905; the bunkers and tramway were built in 1906; ore shipments began in 1907, and since then regular semi-monthly shipments have been made. The first year's shipments were to the smelter at Tacoma, but they go now to the plant of the Tye

Sulzer Mine of Alaska Industrial Co.

Copper Co. at Ladysmith, B. C. With present facilities 100 tons of ore per day can be produced. The expenditures for mining ore and for development are in the ratio of 3 to 4. The mining costs, charged to the tonnage of ore produced in 1908, were \$2.34 per ton; tramming and loading, 30c. per ton. The shipments for that year amounted to 20,732 tons; the shipments for 1909 can hardly be less, and may be greater.

The mining operations are on a mineralized zone that strikes northwest. This zone is 1000 ft. wide in places, but much narrower elsewhere. It has a foot-wall of granite and a hanging wall of limestone. The granite wall is well defined and has a dip of approximately 60°; the limestone wall is not so well defined,

as the ore fades into the lime from the main bodies. The ore occurs in lenses and irregular masses, with garnet, epidote, feldspar, and altered limestone. It contains from 4 to 5% copper and \$1.50 to \$2 gold per ton, generally in chalcopyrite. Streaks and lumps of molybdenite are observed in the garnet and limestone. It does not now appear to be of commercial value. The orebodies are opened by a series of adits, or levels, most of which cut the ore at the surface. The vertical distance between the highest and lowest of these levels is 500 ft. The several higher levels are connected by chutes with the main working levels, which connect with the tramway. In all there is said to be about 12,000 ft. of workings. Faces of ore and stoped-out chambers show ore-lenses 50 to 60 ft. wide. The ore is hard, and drills used in it dull rapidly; it stands well and requires little timbering. The Temple air-electric drills are in use, but a Sullivan compressor and air-drills have been ordered to supplement them. The compressor will be installed at the mine and will be electrically driven. The mineral zone, in its strike southeast, cuts the summit of the mountain, which rises 2000 ft. higher than the mine workings. Following the contact northwesterly 2000 ft. or more from the base of operations, the belt is seen to contain bodies of magnetite, with some copper. The outcrop of this ore is conspicuous. Eight of the company's claims on this part of the mineral zone have been leased for five years to the Tyee Copper Co.. R. G. Mellin has been sent there with diamond-drills to thoroughly prospect the ground.

The Mt. Andrew mine is situated on the south side of Kasaan peninsula. It belongs to the Mt. Andrew Iron & Copper Co., having headquarters at Seattle. Sam Lichtenstadter is manager, with W. C. Freeborn as superintendent. The property was formerly under lease to the Britannia company, but is now being operated by the owners. Since November, 1906, 42,000 tons of ore have been shipped, and the company is now shipping at the rate of 1500 tons per month. The ore is sulphide, assaying 41½% copper, 42% iron, and \$1.25 per ton in gold and silver. There are orebins and a wharf on Kasaan bay, and from this place a 3060-ft. Riblet aerial tramway extends up to the mine. There are, also, two air-compressors at the beach, from which a pipe conveys air to the mine. There is a strong outcrop of copper-iron ore on the surface, along a contact of limestone and syenite, the ore being in irregular bodies. A main working level has been driven from the side of the mountain, cutting 100 ft. below the main croppings; and from this level numerous drifts have been driven to open the orebodies within a large area, the level and drifts aggregating 1000 ft. At various places on the drifts raises have been made to the surface, connecting with open pits. The ore is blasted in these pits, or glory-holes, and sent down through chutes to the drifts, thence conveyed in ore cars to the bins at the tramway terminal. There are 10 of these glory-holes, not all of which are being actively worked at present. Sinking is in progress on the main level, where a compressed-air hoist is being installed. The Mamie and Stevenstown mines are situated a short distance

north of the Mt. Andrew, but these have been inactive for some time.

The It Mining Co. has a shipping mine farther west on Kasaan bay. H. C. Strong, C. H. Black, and John C. Barber are the principal interested parties, Mr. Barber being in direct charge. The ore is chalcopyrite in limestone. About 4000 tons have been shipped since last November, assaying 10% copper at the smelter. It is stated, also, that ore with 10% copper carries \$4 gold and 1½ oz. silver per ton. Recently a Sullivan air-compressor and air-drills were installed. The ore is conveyed to the bunkers at the beach over a surface tramway. The Mt. Andrew and It are 30 to 35 miles by water from Ketchikan.

The Goodro mine, in the same locality, has a strong vein of bornite ore, and will make some shipments as soon as the surface tramway is finished. S. J. Goodro is in charge; J. E. Chilberg, of Seattle, is said to be interested in the property. The Dunton, at Hollis, on an arm of Kasaan bay, is a gold property which is being developed by M. K. Rodgers and associates, who will soon have a small stamp-mill installed at the property.

Dolomi district has some gold and silver-bearing veins of ore, on a contact between dolomite and gneiss; some veins there are entirely in dolomite. The gangue of these veins is quartz, which contains gray copper, with which the gold and silver is associated. The most development has been done on the Valparaíso by the Princeton M. Co., for which B. A. Eardley is manager. John Heerdt is connected with this and other locations there. It is reported that the Niblack mine, on Mora sound, will be re-opened this season. It belongs to the Wakefield estate.

The Gopher-Empire Mining Co., composed of Minnesota and New York people, is represented in this section by E. C. Howard, who is developing some copper and galena claims on Dora inlet, an arm of Chomondeley sound; and who is exploring other parts for the purpose of acquiring properties for this company. Mr. Howard has established an assay office for his own use.

The Northland Development Co. is opening a property on Big Harbor, on the west coast of the island. P. A. Tucker, a stockholder in the company, is in charge of the work. The vein of copper ore lies between limestone and quartzite. The gangue is schistose. There are 250 ft. of development. A test lot of three tons of ore shipped to the smelter showed, on sampling, over 10% copper. A tramway 1800 ft. long may be erected later in the year.

Gold is found at various places along the southern shores of Lake Victoria Nyanza and in the Wembäre Steppe between Tabora and Muanza, German East Africa. Near Sekenke, in the eastern part, a new goldfield has been discovered. The gold exists in quartz veins in granite. The veins are very numerous and contain gold, though not always in great quantities. Operations are already sufficiently advanced for the erection of a plant to work the ore. The total value of the gold exported in 1907 amounted to some £1566, the whole of it going from Muanza by way of the Uganda railway and Mombasa. — *Mining Journal*.

Level and Stope in Sulzer Mine.

FLUORSPAR.

By F. JULIUS FOHS.

*Centrally located with relation to the largest iron and steel-producing districts of the United States, the fluorspar-deposits of Kentucky possess increasing interest and importance. The value of fluorspar in the manufacture of iron and steel depends upon its ability to form two types of allied slag-products, whereas an acid or a basic flux forms only one. It first forms volatile acid products, in which fluorine is the controlling factor, and then basic slag-forming compounds, in which calcium is the characteristic constituent. Fluorspar is chiefly serviceable, therefore, in the 'basic' processes of steel manufacture, because both the products formed by it are destructive of acid furnace or converter linings. Basic slags, basic furnace linings, and gently oxidizing conditions are necessary if the most favorable results are to be obtained from the use of fluorspar in the making of iron and steel. The thorough purification of iron requires the elimination of silicon, sulphur, and phosphorus, and with these the fluorine of the spar forms fluorides, which are volatile acid compounds, while its calcium forms silicates, sulphides, and phosphides, which are basic slagging compounds. These reactions, and those which occur between limestone and phosphorus, are as follows:

- (1) $2\text{CaF}_2 + \text{SiO}_2 = 2\text{CaO} + \text{SiF}_4$, and
- (2) $2\text{CaO} + 2\text{SiO}_2 = 2\text{CaSiO}_3$; or
- (3) $2\text{CaF}_2 + 3\text{SiO}_2 = 2\text{CaSiO}_3 + \text{SiF}_4$.
- (4) $2\text{CaF}_2 + 3\text{S} = 2\text{CaS} + \text{SF}_4$.
- (5) $2\text{CaF}_2 + 3\text{P} = 2\text{CaP} + \text{PF}_3$.
- (6) $3\text{CaCO}_3 + 3\text{SiO}_2 = 3\text{CaSiO}_3 + 3\text{CO}_2$.
- (7) $3\text{CaCO}_3 + 3\text{S} = 3\text{CaS} + 3\text{CO} + 6\text{O}$.
- (8) $3\text{CaCO}_3 + 3\text{P} = 3\text{CaP} + 3\text{CO} + 6\text{O}$.

It will be seen from equations (1) and (2) that silica combines with calcium fluoride and sets free two molecules of calcium oxide, which will satisfy two additional molecules of silica, the result being that of equation (3). In the case of sulphur and phosphorus there is a direct interchange of constituents. The reactions attending the joint use of fluorspar and limestone would be expressed by combining equations (3) and (6), (4) and (7), (5) and (8).

The volatilization by fluorine, as shown by these reactions of one-third of the difficultly fusible constituents of slag and the resulting increase in lime content, seem to present the following distinct metallurgical advantages: (1) the slag is more basic, fusible, and liquid; (2) fusion is effected at a lower temperature, which, together with the heat-yield from the formation of fluorides, reduces fuel consumption; and (3) the concentration of the slag increases the metal output.

Fluorspar has a very limited value, if any, in assisting in the removal of carbon or manganese. An excess of this flux over the quantity required to flux the silica, sulphur, and phosphorus, would alloy graphite and manganese with the iron and reduce silica to silicon; and fluorides would be formed which, in the reaction with the hydrogen of the fur-

nace gases, would be reduced to metals and hydrofluoric acid. Such an employment of fluorspar requires very careful manipulation; but it may be made to give, as desired, either pure iron, iron of slightly altered qualities, or a distinct alloy.

In quantitative effect, fluorspar has a distinct advantage over other basic fluxes—about two to one as compared with calcium carbonate, the cheapest of them. Moreover, by reason of the volatilization of one-third of the impurities, it forms only two-thirds as much slag as limestone. But it costs eight or ten times as much as limestone; and large quantities of it would produce effects opposite to those desired. Hence the best present practice is to use as a flux in iron and steel metallurgy a comparatively large proportion of limestone and a small proportion of fluorspar (in order to secure the peculiar effects of the latter). This practice is not very expensive. For example, if limestone costs \$0.50 and fluorspar \$5 per ton, the use of 3% of fluorspar in the flux would make the cost per ton of flux 63.5c., instead of 50c., or only 9% of increase in the cost of the flux for each 1% of fluorspar. The substitution of other basic fluxes for part of the limestone will not interfere with the action of the fluorspar; but some of them, like dolomite, require a greater percentage of fluorspar to lower their melting point.

The net fluxing value of a crude fluorspar may be determined with sufficient accuracy by deducting the silica plus 2 units of basic impurities or 1 unit of calcium fluoride for each unit of silica. Thus, in a material containing 91% of calcium fluoride, 2 of silica and 7 of calcium carbonate, alumina, iron oxides, etc., the 2 units of silica could be regarded as practically neutralized by 4 units of the basic fluxes, leaving as the net flux 91 of calcium fluoride and 3 of basic compounds; whereas, if the material contained 91 calcium fluoride and 9 silica, it would be necessary to deduct 9 units of the fluoride to satisfy the silica, leaving as net flux 82% of calcium fluoride.

Fluorspar is commercially obtainable in four grades. Stated in percentage, the first carries from 96 to 98 calcium fluoride, with not more than 2 silica; the second, 90 fluoride, with less than 4 silica; the third, 80 fluoride, with a maximum of 12 silica; and the fourth, about 60 fluoride, with a maximum of 15 silica. Concerning these grades, it may be added that the first, by reason of its cost, is little used in iron and steel works; the second is the most available for that purpose, though in some cases it might be economical to require, and pay for, a material considerably lower in silica than 4%. The third is likely to give, after due allowance for the basic constituents, about 78%, and the fourth a minimum of 60 fluoride with 10% of available basic flux. The economic limit for the purchaser is about 8% of silica; and the third and fourth grades should be purchased only on the basis of their net fluxing value, as determined by the method suggested above.

The proportion of fluorspar which can be used with advantage is thus seen to be a variable, dependent upon the price of the crude material, the process in which it is employed, and the impurities of flux, fuel, and ore. The calculations of the furnace man-

ager should be made accordingly. It may be said, however, that where pure limestone is the main flux, from 1.5 to 8, on the average 3, of fluorspar to 100 of limestone is sufficient to secure the main advantages of the compound flux; for magnesian limestone, from 15 to 30% of the fluoride may be required. The fluorspar-limestone flux may be useful in the manufacture of pig-iron, wrought-iron, crucible-steel, basic bessemer and open-hearth steel, iron and steel alloys, and ordinary and malleable iron castings. In rare instances, and in small quantities, it may be serviceable in the acid steel processes also. In blast-furnace practice it has been, as yet, but little used, for the reason that its advantages are not generally understood, and its cost has been regarded as prohibitory. As has been shown above, however, the additional expense of using a certain percentage of fluorspar is not great in comparison with the economic and technical benefit thus secured; and its use may therefore reasonably be expected to increase. It is specially advantageous in the smelting of highly silicious ores, and for the purpose of 'thinning' a too limy slag—for which it is used by the Illinois Steel Co. It may be blown as a powder through the tuyeres, or intimately mixed with the charge. It should be of service in smelting iron ores in the electric furnace, since it lowers the temperature of fusion. It is known to be serviceable for this purpose in other electric-furnace operations, as in the Lungwitz zinc process, in making alundum, carbolite, and so forth.

In the bessemer process, because of the strongly oxidizing conditions, fluorspar is little used. But even here, it appears, according to Howe, to assist by melting the lime rapidly, in making an effectively basic slag, with which phosphorus combines readily during the early part of the operation. It is in the basic open-hearth process that American fluorspar is mostly used, especially in plants which produce steel for rails, tubing, or castings, for which the highest quality of open-hearth steel is required. In this process, fluorspar is used to facilitate the liquefaction or thinning of the slag (especially to help melt the flux or limestone), thus reducing by about half the time required for the melt. It is only to be used when the limestone is soft and white-hot, floating at the top of the bath, usually about two hours prior to the completion of the heat. If used sooner, it makes the slag too thin. If too much limestone is charged, fluorspar is helpful in converting it to slag quickly. An excess of fluorspar thins the slag too much, with harmful results, such as the rapid oxidation of the carbon, which reduces the temperature; the excessive oxidation of iron, which causes losses of metal, and also thins the slag; and the too-rapid oxidation of other impurities (such as phosphorus and sulphur), which gives them opportunity to become again reduced and alloyed with the metal. The per cent of fluorspar to that of limestone in this process varies from zero to 8, with 3% as an average. Where the slag is sufficiently thin, or if sufficient scale, iron oxide, has been used, no fluorspar at all may be required. If the slag is thick and melts slowly, a little fluorspar is shoveled in. An intelligent furnace man requires less fluor-

spar than a careless one. The requirement of fluorspar per furnace is about 100 tons per year. 'Gravel' fluorspar is used, usually of the second grade.

The procedure in open-hearth practice, according to a private communication from J. W. L. Kerr, is as follows: Magnesite and dolomite are first put in as furnace-lining. Afterward 6.5 tons of limestone and 25 to 35 tons of scrap-iron are put in and heated together. At the right heat, the melted pig-iron necessary to make the total charge 60 to 70 tons is added. Lake Superior hematite is then added until the carbon is reduced from 0.18 to 0.08%. Pieces of limestone come to the surface in blocks; and fluorspar is used in amounts varying from 200 to 1100 lb., or about 0.15 to 0.8%, per charge, both to break up the limestone blocks and to reduce sulphur and phosphorus. At the Illinois Steel Co.'s South Chicago Works the practice, according to a private communication from George L. Danforth, Jr., is to use from 0 to 15 lb. of fluorspar, 6 lb. on the average, to 200 lb. of limestone per ton of basic open-hearth steel produced, the iron charged being half pig, half scrap. No actual weights are taken, and the gravel fluorspar is shoveled in as needed when the limestone is at the right heat. Where 50 tons of cheap scrap-iron are used, the use of 2.5% of fluorspar is said to give as fine steel as the best pig produces. Carr proposes the addition of 13 lb. of fluorspar with 300 lb. of limestone to 1227 lb. of pig-iron and steel scrap for each ton of basic open-hearth cast-steel produced.

Fluorspar is a valuable flux in the preparation of iron and steel alloys, and here its value depends on its use in excess in conjunction with a highly basic flux in reducing carbon, manganese, silicon, chromium, nickel, etc., as previously explained. In the ordinary blast-furnace, ferro-silicon, containing as much as 10% of silicon, can be produced from any silicious ore in this manner. Likewise, spiegeleisen, low or high ferro-manganese, or metallic manganese, may be produced. In the last case, the flux consists of alumina, lime, and fluorspar.

The objections that have arisen in some quarters to the use of fluorspar in foundry practice are due to the ignorance of its capabilities and manner of use. The dealers who sell fluorspar as a flux under high-sounding names, making extravagant claims as to its effect in extremely small quantity, and charging correspondingly high prices for it, are chiefly to blame for this. That its use alone has proved unsatisfactory is not surprising. When it has been used in conjunction with limestone, the failures have been due to an insufficient amount of total flux, usually with the additional error of an improper proportion of fluorspar and limestone in the mixture. This explains the unsatisfactory results of the Foundryman's Laboratory tests, reported by N. W. Shed, in which it was sought to reduce sulphur and phosphorus without making allowance for either the fluorspar or the limestone which would necessarily flux part of the silica of both the coke and the pig-iron—a neutralization which left no fluorspar available to reduce the sulphur or the phosphorus.

The present foundry practice is to use pure limestone for flux in the cupola, 100 lb. of limestone to a

2-ton charge, and either no fluorspar at all or only such small quantities of it as are necessary to help bring about a quick melt of the limestone. If no pure limestone is available, then dolomite is used, and in conjunction with this fluorspar is indispensable. In many foundries, especially in the small ones, only a single 2-hour heat is made per day, so that the time consumed is immaterial. In the large foundries continuous heats are demanded, with an output of at least 15 tons per hour. The use of fluorspar reduces the length of time required for each melt. Where fluorspar is used with dolomite, only one-half as much time is required as for dolomite without fluorspar. The type of cupola used makes little difference.

A typical practice in this respect is that of the Crane Co., Chicago, which, after repeated attempts to get pure limestone for flux, settled upon the use of dolomite and fluorspar in the ratio of 25 or 30% of fluorspar to 100% of dolomite. Analyses of typical fluxes used are as follows:

	SiO ₂	P	Fe ₂ O ₃ + Al ₂ O ₃	CaF ₂	CaCO ₃	MgCO ₃	PbS	ZnS ZnCO ₃
Fluorspar,	1.37	0.006	0.50	96.75	0.08	1.69
Dolomite,	1.08	0.007	0.68	53.50	45.19

Such fluorspar has 90% of available calcium fluoride, for some fluorspar is necessary to flux the lead and zinc as well as the silica. A fluorspar is specified for this use that contains less than 2% of silica, and the dolomite must not contain a greater amount. This means that only No. 1 fluorspar can be used. Lump is purchased, as it is likely to contain less silica. After the fluorspar reaches the foundry it is broken into pieces not larger than the size of an egg, since larger pieces would be likely to strike the lining and, combining with it, destroy it. The cupolas have the usual fire-brick linings, which, if the precaution is observed, are but slightly if at all affected. The sulphur is not likely to be reduced materially by the use of fluorspar if there be less than 1%, but if there be more the reduction of sulphur will be marked.

Aside from its use in the cupola, a small percentage of ground fluorspar, placed at the bottom of the ladle, serves to slag impurities, which rise to the surface as a heavy mass, and, after stirring to insure perfect mixture, are skimmed off. According to R. C. Hills, gray iron so treated produced not only a softer iron, but when molded into bars and broken on a testing machine, showed 11% greater breaking-strain than bars made from the same pig not so treated. For malleable iron, similar treatment showed a more malleable iron with an increased tensile strength and an increase in elongation over ordinary malleable iron. Frogs made of this material cracked to a far smaller extent than ordinarily.

The use of fluorspar in the iron and steel industry is extending. At present, the percentage of fluorspar consumed is one-half of 1% of the quantity of limestone flux used in America; but there has been a small but steady increase in its use during recent years. This is chiefly due to the extension of the basic open-hearth steel manufacture. Fully 80% of the American fluorspar is consumed in basic open-hearth plants. Of this quantity, more than 90% is in the 'gravel' form.

ELECTROLYTIC REFINING OF GOLD.

B. T. K. ROSE.

*The separation of silver and other impurities from gold by electrolysis in a solution of hydrochloric acid was suggested by Charles Watt of Sydney in 1863. He proposed to apply the method at the Sydney Mint, and claimed to have discovered means of preventing the evolution of chlorine from the anode, but no steps were taken to test his process. In 1878, Wohlwill of Hamburg introduced his process at the Norddeutsche Affinerie, and it has since been applied elsewhere in Germany. It displaced the sulphuric acid process at the Philadelphia Mint in 1902, and at the Denver and San Francisco Mints in subsequent years, and is in process of being installed at the Ottawa Mint. It has made little progress in other countries.

In the Wohlwill process the electrolyte is a solution of gold chloride containing from 25 to 60 grams of gold per litre, and from 20 to 100 c.c. of concentrated HCl per litre. It is heated to a temperature of about 60 to 70°. The anodes consist of impure gold, containing not more than 60 or 70 parts of silver per 1000, and the cathodes of pure sheet gold. The anodes dissolve partly as trivalent gold, forming HAuCl_4 , and partly as monovalent gold. The AuCl formed at the anode is partly decomposed into AuCl_3 , and metallic gold, which falls to the bottom, but some of the monovalent gold ions reach the cathodes. The higher the current density the more trivalent gold is dissolved and the less AuCl is formed, so that there is less gold in the slime at the bottom. The current employed in the United States is from 300 to 600 amperes per square metre of anode-surface. The deposition of gold at the cathodes is greater than the amount dissolved at the anodes, owing to the presence of impurities in the unrefined gold, so that it is necessary to add chloride of gold to the solution at intervals. Silver is converted into AgCl at the anodes, and falls to the bottom of the vessel, or is in part dissolved. The anodes may contain up to 150 per 1000 of silver, but if such a large proportion is present it is necessary to scrape the silver chloride from the surface of the plates. Platinum is dissolved with the gold and accumulates in the solution, from which it is recovered in the ordinary way. The deposited gold is nearly pure.

The electrolyte is circulated by mechanical means, and is renewed when it has been made foul by the accumulation in it of copper, palladium, etc. Lead makes the deposited gold impure, but may be rendered insoluble by the addition of sulphuric acid.

Apart from observations on the technical details of this process, the points on which information is particularly required are: (1) the time required to complete the process. This is most important, because of the loss of interest on the gold under treatment. The chief objection to the application of this process in England is the fear that the process is too slow. (2) The cost for labor, power, etc. (3) Whether, if speed is unduly increased, the gold is likely to be of bad quality, contaminated with lead or other elements which would make it brittle.

HISTORICAL GEOLOGY OF CALIFORNIA.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM FORSTNER.

(Continued From Page 858, June 19.)

Tertiary (Cenozoic).

Sierra Region. During the Eocene the Cretaceous erosion period of the Sierras continued, and the Eocene is not represented in the Sierras north of the Merced river. In the extreme southern portion, near the Tehachapi range, however, the Eocene Tejón becomes prominent. At or near the close of the Eocene an orographic disturbance took place in the Sierra region. At that period the Sierra Nevada was a range of low relief, and erosion took place with moderate intensity.⁴⁴ A zone of normal faulting was inaugurated along the eastern slope of the Sierra,

Cemented Gravels Covered by Boulder Clay. Minersville.

due to the deformation of the Great Basin, as a thick series of Miocene beds but no Eocene beds were laid down in the low trough formed east of the Sierra. It is highly probable that this fault was inaugurated either within or at the close of the Eocene.⁴⁵

The Auriferous Gravels. The Lower Miocene stream-beds had a shallow trough-like form. In their centre is frequently found a deeper cut, indicating a short period of active erosion just before the beginning of the Gravel period. At this time, probably the beginning of the Miocene, the streams became charged with more detritus than they could carry; the character of the gravel accumulations point clearly to a somewhat rapid stream, and that they are due more to rapid overloading than to a low grade in the rivers.⁴⁶ These conditions can be best ex-

pained by a relative elevation of the high Sierra, leaving the lower slopes unchanged, and this disturbance may be synchronous with the disturbance along the east slope of the Sierra Nevada. During the Miocene this accumulation of gravel in the river-beds and on adjacent benches continued up to a present elevation of from 5000 to 6000 ft., while above that elevation erosion still continued. These formed the gravels of the first period. Their age was formerly supposed to be Pliocene, but later investigation has proved it to be Miocene; they are chiefly composed of white quartz pebbles and light colored clays and sands, with minor lava flows of rhyolite, and are free from volcanic pebbles. They are often called the 'white-quartz gravels'. Their lower portion is a

Manzanita Gravel Mine, Nevada City

Drift Mine, Lewiston.

conglomerate of pebbles and boulders, often of large size, usually of a blue-slate color, from which it derives the name of 'blue gravel'.

The first Miocene eruptions consisted of flows of rhyolite, which poured down the valleys, becoming mixed with the detrital material on the way. Lower down they are found as semi-volcanic sands, clays, and gravels, forming fine-grained beds of a brilliant white color, locally called 'pipe clay'. These rhyolite flows usually confined themselves to the valleys and formed a capping over the gravel from 50 to 150 ft. thick. In places this tuffaceous material is overlaid by a basalt flow, forming table-lands; these older basalts are, however, not represented in the section between the Yuba and the American rivers. After the rhyolite and older basalt flows came a period of erosion, with some minor intermediate volcanic outbursts, during which the rivers had to seek new channels, confined generally to the older valleys. During

⁴⁴Folio 43, U. S. G. S.

⁴⁵17th Ann. Rep., U. S. G. S., Pt. I, p. 530; 40th Parallel Survey, Syst. Geol., Vol. I, p. 744; and Am. Jour. of Sci., Vol. 38, p. 262.

⁴⁶Bull. Geol. Soc. of Am., Vol. IV, p. 265.

this period were formed the channels of the intermediate period. The pebbles of these channels are chiefly of pre-Cretaceous rocks. These gravels are usually dark in color, are less auriferous than the 'white quartz gravels', and are locally known as 'bull' or 'bastard gravels'. After this period of relative quiescence of the volcanoes in the high Sierra resumed activity, and a period of intermittent andesitic flows succeeded. Again the rivers were displaced, and whenever the intervals between the eruptions permitted, they resumed the cutting of their channels through the accumulated silt. The gravels of the volcanic period form the gravels of the second period, namely, that of the 'volcanic cement gravels', and they contain abundant volcanic pebbles. The plant-remains in these gravels are not abundant; they are probably Upper Miocene or Lower Pliocene. All these channels were finally buried by the last great andesitic flows, which covered the lower and middle slopes of the Sierra Nevada to such an extent that only isolated peaks and ridges protruded. These came down as successive mud-flows, settling soon into a hard, compact, gray or brown rock, a tuffaceous breccia, containing large, usually angular boulders of andesite. This eruption is assumed to close the Pliocene, and forms the horizon by which the Neocene and Pleistocene accumulations are separated. The Neocene shore-gravels are of the same age as the later auriferous river-gravels, but were deposited in the waters of the gulf which covered the Great Valley of California.⁴⁷ In the latter part of the Pliocene the dislocation at the eastern base of the Sierra Nevada was greatly accentuated. The northern portion of the Sierra Nevada consists of three orographic blocks, while in the central and southern portions the range appears to be formed of one great orographic block, which is continuous with the western block of the northern end.⁴⁸ Along the western foothills, and at the base of the Sierra Nevada, the Miocene is represented by the Ione formation, consisting of beds of clay and sand, with layers of lignite. The clay is locally used for the manufacture of pottery.⁴⁹ In great extent it is covered by later sediments. In the northern part of the western foothills, the Ione is overlaid by the Pliocene Tuscan tuffs, consisting chiefly of basaltic tuffs, with fragments of andesitic lavas and older rocks.⁵⁰

Northern California. At the close of, or perhaps a little later than, the middle of the Chico, northern California and southern Oregon were raised above sea level and were subjected to erosion, and as far as known no Eocene deposits occur in northern California except one fresh-water deposit in Hay Fork valley, Trinity county.⁵¹ On the northwest border of the

Sacramento valley is a well marked base-level plain of erosion, which runs from Elder creek to near the Great Bend of the Pit river, a distance of about 100 miles. It passes to the east beneath the lavas of Lassen peak, suggesting that it may reach the plateau of the interior region, now covered by volcanic material. Within northeastern California and the adjacent part of Oregon are vast stretches of level places which are not far from the same altitude above the sea. As far as known, all the surrounding hills in that region are of lava. The largest part of this plain has been carved on the up-turned edges of the Cretaceous. The erosion necessary for its development out of the topography resulting from the uplift at the close of the Cretaceous must have occupied a long interval of time, possibly beginning in the late Cretaceous and continuing through the Eocene and the earlier Miocene.⁵²

The Miocene is represented by the Ione formation, which, being well stratified, must have been laid down in an extensive body of water. Due to the above-mentioned post-Cretaceous uplift, the ocean was excluded from the region of the present Sacramento valley north of Marysville, and from the Lassen strait, and this region, as well as a large area in eastern Oregon, was covered by a large body of fresh water, which has been called Piute lake. The Ione formation consists of gravel, sand, and clay, partly but feebly indurated into conglomerates, sandstones, and shales, with some seams of lignite. The unconformity of the Ione with the underlying Cretaceous on the west side of the Sacramento valley is much more marked than in the Lassen Strait region, showing that the post-Cretaceous disturbance was much stronger in the Klamath district than to the east of it.⁵³ Within the Klamath mountains are five isolated brackish or fresh-water Miocene deposits, of which that of Hay Fork is the chief.⁵⁴ There is reason to believe that the earlier eruptions in the Lassen Peak region occurred in the Pliocene, and may be contemporaneous with the late andesitic eruptions in the Sierra Nevada. Their tuffs (the Tuscan) were unquestionably deposited about the same time near the shore of Piute lake. These Pliocene eruptions must have been accompanied by a disturbance of the entire region, for the Tuscan tuffs rest unconformably upon the eroded surface of the Ione. Subsequent to their deposition a differential uplift, being greatest eastward, raised the tuffs above the level of the lacustrine waters, and formed a monoclinal fold at the western limit of the region, running from Battle creek to Deer creek. Toward the close of the Miocene began a series of differential uplifts and intervening periods of quiescence and erosion. This lasted during the later Miocene and Pliocene and persisted during the Pleistocene.⁵⁵

COSTS AT THE OSCEOLA MINE.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

The cost per ton of ore hoisted by the Osceola Consolidated Mining Co., in Michigan, for the years 1905, 1906, and 1907 were as follows:

Items of Expense.	1905.	1906.	1907.
Mining	\$1.055	\$1.123	\$1.282
Rock-house	0.067	0.071	0.068
Transportation	0.079	0.080	0.084
Stamping	0.155	0.128	0.109
Surface	0.008	0.012	0.027
Office	0.012	0.010	0.015
Incidental	0.105	0.111	0.241
Total without construction..	\$1.482	\$1.535	\$1.826
Construction	0.117	0.119	0.098
Total, including construction	\$1.599	\$1.654	\$1.924
Waste sorted out	8.3%	7.2%	5.2%

Of the above items, that for mining only is given in detail, as shown below:

	—1905—	—1906—
Underground contracts.	\$0.540	\$0.560
Tramming	0.186	0.205
Timbering:		
Labor	\$0.026	\$0.025
Supplies	0.020	0.017
	0.046	0.042
Compressor:		
Labor	0.033	0.030
Power supplies	0.030	0.027
Miscellaneous	0.020	0.016
	0.083	0.073
Miscellaneous:		
Labor	0.110	0.132
Power supplies	0.072	0.060
Miscellaneous supplies	0.034	0.050
	0.217	0.242
Total mining expense..	\$1.055	\$1.122

For the first eleven months of 1907 mining expense is differently divided, as follows:

Underground contracts:	
Labor	\$0.459
Power	0.084
Miscellaneous	0.113
	\$0.656
Tramming	0.316
Hoisting:	
Labor	0.040
Power, etc.	0.076
Miscellaneous	0.028
	0.144
Miscellaneous:	
Labor	0.103
Power supplies	0.028
Miscellaneous supplies	0.036
	0.167
	\$1.283

The table below gives the number of tons stamped, and the product of the Osceola mine in 1905, 1906, and the first eleven months of 1907:

	1905.	1906.	1907.
Ore stamped, tons.....	1,007,200	1,016,240	767,665
Concentrate produced, lb..	24,458,000	23,910,000	17,398,700
Barrel copper produced, lb.	396,391	326,281	2,037,756
Total product, lb	24,854,391	24,236,281	17,602,458
Total ingot copper, lb....	18,938,965	18,588,451	13,358,262

LOW PRESSURE STEAM TURBINES.

By I. N. HOLLIS.

*While the steam turbine is admirably adapted to a low vacuum, the steam engine can not make economical use of low pressures, on account of the enormous size of cylinder required. The volume of one pound of steam at 175-lb. pressure is 2.608 cu. ft., and that at 1/2-lb. pressure is 648.6 cu. ft. For example, a compound engine with cylinders 36 by 72 by 48 in. would require a third cylinder of at least 200 in. diam. to make use of steam expanded down to 1/2-lb. pressure. Even if it were possible to build and operate cylinders of such dimensions, the loss by condensation, radiation, and friction would more than offset the gain from the use of greater ranges of expansion. Hence compound and triple-expansion engines can never take full advantage of the lower vacuums. On the other hand, the high-pressure part of a turbine cannot make as effective use of steam as the low-pressure part, for two reasons: In the first place, the percentage of leakage by the blades is much greater; and in the second place, the rotation-losses due to the higher density of the steam are large. The steam engine and the turbine are then natural companions, one for high and the other for low pressures, although it is still extremely doubtful if the two should be designed and built for combined operation in a new station.

The percentage of available energy actually realized in practice varies within wide limits, depending upon the conditions and upon the size of the engine. A good performance for the ordinary compound engine is about 70% efficiency in the cylinders, and the return of energy for one pound of dry saturated steam is then 0.70 × 204,300 = 143,010 foot-pounds, equivalent to 13.84 lb. of feed water per indicated horse-power per hour, or to 20.28 lb. per kilowatt-hour, at the switchboard. If the efficiency of a noncondensing compound engine be taken at 66 at the switchboard, the energy actually realized will be 91.368 foot-pounds, and the steam consumed about 29.05 lb. per kilowatt-hour. This is a better rate than is commonly realized in non-condensing engines, but the range of pressure is higher.

In case the steam were taken into a low-pressure turbine after having done its work in the steam engine, the energy actually realized in addition to that already yielded at the switchboard, would be about 0.68 × 138,000 = 93,840 foot-pounds, thus requiring for the turbine alone 28.28 lb. steam per kilowatt-hour. If the return of energy from the turbine be added to that from the engine, the feed-water per kilowatt-hour would be 14.33 lb. The vacuum has been taken rather better than is to be found in the average turbine station; on the other hand, the efficiencies assumed are below the best that can be realized with engines and turbines of large power.

Hardness in steel and iron varies with the composition. On the scleroscope scale bessemer rail shows hardness of about 30, manganese steel shows hardness of 40 to 50, chilled cast-iron, 65 to 75.

*Abstract from article in *Engineering Magazine*.

PHOTOGRAPHY IN MINING.

Written for the MINING AND SCIENTIFIC PRESS

By J. B. LANFIELD.

The large use made of photographs in all reports, and the many types of apparatus available, perhaps warrant the following suggestions. The camera has become a useful, not to say necessary, instrument in the mining engineer's equipment, and as such, care should be taken in its selection and skill employed in its use.

There are two important questions to be decided in the selection of a camera, the question of size and the question of plate versus film. The latter is not easy to settle, for there are strong arguments on each side. The film has the great advantage in portability. It is light and does not break, and fresh rolls can be inserted in the camera very quickly. On the other hand, plates keep much better (in tropical countries films are almost useless), and can be had in faster speeds, and in general the results obtained are more satisfactory. In fact the proportion of fine negatives is so much greater that a dozen plates are usually equal to two or three times that number of films. Plates may be easily put into plate-holders in daylight by means of a changing bag, and can likewise be developed in a tank without a dark-room. If packed snugly in the boxes in which they come there is little danger of breakage. For my own part I much prefer to take plates with me, but if anyone prefers to use a film camera in the field, I strongly recommend him to precede this by practice with a plate camera. Mining photography, especially on the geological side, demands definition and tone values that can only be obtained by skill in focusing and exposure, and, contrary to general belief, the kodak seldom achieves fine results except in the hands of the expert trained in stand photography. As to the question of size, the best English practice has given up the use of large cameras. It is much better to take a small, sharp negative and enlarge from it. The fact is that the engineer really needs two cameras, one a small pocket camera, always ready to catch the chance view without the delay incident to taking out of case and focusing, and a regular stand-camera complete, capable of being used for any kind of photography. For the first a No. 1A folding pocket kodak, or something similar, answers the purpose. For my own part, I use a Newman & Guardia 'Sybil' camera, $2\frac{1}{2}$ by $3\frac{1}{2}$ in., with a Zeiss Tessar lens, the most compact camera made.

The stand-camera should be a substantial box, simple and strongly built. In general the German boxes are too complicated with ingenious devices which, unfortunately, get out of order easily. The boxes made in America are seldom strong and durable. A teak-wood box, brass bound, is best of all, as it is not affected by changes of climate. It should have a bellows of good length that can be extended for tele-photo work. Do not economize in the matter of a lens; buy a first-class anastigmat of fairly short focus—short enough for underground pictures—and preferably one which can be changed to long focus by removing the front section. This obviates the necessity in most cases of a separate tele-photo

lens. A fine all-round lens is the Goerz Dagor double anastigmat, Series III, working at F. 6.8. The stand-camera should not be large—not larger than 4 by 5, and better $3\frac{1}{4}$ by $4\frac{1}{4}$, or what is termed in England 'quarter-plate'. It is absurd to carry around a 5 by 7 or $6\frac{1}{2}$ by $8\frac{1}{2}$ camera with its complement of plates, when the smaller size negatives enlarge to 8 by 10 inches and make just as good a picture if not better. Do not fail to equip your camera with a color screen (or ray filter) to secure the proper tone values for colors in nature. One need not call attention to the necessity of this for photographing rocks that vary in color and that would without this precaution appear identical in the picture. Do not forget that with the color screen you must double or treble the exposure, according to the density of the screen. It is well also to equip your camera with the color screen required for using the Lumière autochrome plates for color photography. The outfit should also include an exposure meter—Wynne's or Watkins'—to determine the length of exposure and thereby save many a plate that would otherwise be wasted, plate-holders for a dozen plates, a focusing cloth in the form of a sleeve gathered with an elastic tape at one end to fit over the camera back, and having a piece of leather at the other end with two eye-holes cut in it, and elastic tapes to loop over the ears, and a firm wooden tripod. I have long since given up the tremulous, easily-broken, aluminum ones.

Out of a veritable museum of cameras which I have indulged in I have settled down upon an English box, the Sinclair 'Una' camera, $3\frac{1}{4}$ by $4\frac{1}{4}$ in., as altogether the most satisfactory. With it is a strong leather case in which I carry it strapped to the horn of my saddle when I am in the field. A nickel-plated developing tank, which measures 2 by 4 by 6 in. and takes both $2\frac{1}{2}$ by $3\frac{1}{2}$ and $3\frac{1}{4}$ by $4\frac{1}{4}$ plates; two or three packages of '3 $\frac{1}{2}$ -A' kodak developing powders, a pound or two of acid hypo fixing powder and some flash-light powder, and my equipment is complete. It takes up very little room, and even with six dozen plates of each size is not heavy. With this equipment I can get exactly the picture I need. If it is necessary to photograph a mill or a dump on a steep hill-side I can cross the valley, and by using the tele-photo lens and extending the bellows, draw the object near, when ordinarily it would show but a speck on the plate. Again, I can use the same tele-photo lens to take a picture of a small crystal or specimen, magnifying it so as to cover the whole plate. Underground photography is not easy, as it is frequently very difficult to find a position from which a desired face can be taken. In using flashlight for this work, do not burn it all in one place; divide the required quantity in two and set it off on either side of the camera; this will give you a picture of the face without deep shadows.

In conclusion, take every care not to let the slightest ray of light reach your films or plates in changing or developing; focus carefully and expose accurately; the result will be that you will have a good negative to show for practically every exposure, instead of the small percentage obtained under the old 'you push the button and we do the rest' system.

MONTREAL RIVER DISTRICT.

By W. H. COLLINS.

*A widely circulated and seemingly reasonable opinion holds the diabase responsible for the valuable silver-cobalt deposits of the region. The testimony of the Montreal River district as yet known supports this belief.

Early in August a discovery of native silver was made just west of Gowganda lake, and recorded at Elk Lake early in September. Up to that time only a small number of prospectors had been at work in this locality, but immediately following the news of the discovery came an influx of several hundred men. In a few days all the promising country for a distance of three miles west of Gowganda had been staked, and search instituted for mineral deposits sufficient to validate the claims. The results on the whole have been highly satisfactory. At the time of my leaving the district I knew of at least four bona fide silver discoveries. At that time systematic prospecting had scarcely begun, the country was everywhere heavily forest-covered, and exploration was impeded, even rendered somewhat hazardous, by the presence of forest fires, so that intimate acquaintance with the area and its possibilities was very difficult to obtain. However, something has been learned concerning the geological structure and the mineral possibilities as visible at the surface. Westward from Gowganda lake the formation is Huronian, traversed in a north and south direction by three elongated bodies of diabase. The more easterly occupies the peninsula between the two long northerly bays of the lake and extends thence northward for about a mile. It has a maximum width of 60 chains. A central mass 7 miles long and about 40 chains wide extends parallel to the west bay and at a distance inland of less than half a mile. A westerly body of about equal dimensions extends from Elkhorn to Firth lake, being traversed by the chain of lakes used in traveling from Gowganda to the West branch. Various fingers and dikes extend from each of these bodies.

In the easterly body, up to the end of September no silver had been found, although a considerable number of mineralized veins were being examined by trenching. These veins occupy fissures in diabase and vary in width from a few inches to 2 ft. The largest of these was reported by the owner, Mr. McLaughlin, to be continuous for a quarter of a mile. The vein matter is, peripherally, quartz, with a central filling of calcite, the relative proportions of the two minerals being quite variable. Chalcopyrite occurs, often abundantly, in all of them, pyrite less frequently. Cobalt bloom is largely in evidence, and on the property of Mr. O'Reilly smaltite was being obtained in small amounts, together with native bismuth. In one vein the calcite was strongly impregnated with minute crystals of magnetite.

The central diabase body has already been proved to be, judging from the surface indications, richly silver-bearing. On a group of four claims owned by Messrs. Mann, Milne, and associates, a vein was seen

in which native silver occurs plentifully. The calcite gangue had been weathered out, leaving, in a diabase bluff, a crevice about 5 in. wide filled with decomposed earthy matter. Silver formed a discontinuous vertical sheet as far as the vein had then been uncovered, the average thickness of this sheet being about $\frac{1}{4}$ in. The lower undecomposed portion of the vein had not been exposed. At other points on these properties native silver, small quantities of argentite, and a 1-in. vein of solid smaltite had been found. Bloom, chalcopyrite, and galena were widely distributed. Farther south, native silver had been obtained in good quantity at the surface by Mr. Dobie and his partner. At the extreme south end of the mass F. A. McIntosh was surface stripping upon a group of seven claims, but at that time without important result. After my departure from the field valuable silver veins were discovered on this property. Silver had also been obtained in the western mass by W. H. Margueratt, the deposit occurring on Margueratt lake near the middle of the diabase body.

Native silver has therefore been proved to exist at points distributed over an area of about 10 sq. m., in much the same mineral association as at Cobalt and neighboring camps. In this case all the finds yet recorded are within the diabase. The Huronian, however, has not been proved to be unmineralized, prospecting having been confined almost wholly to the diabase areas. The aplite dikes have not yet been proved to carry more than a little disseminated smaltite and chalcopyrite, although in James township, not far away, they are ore-bearing. Although not valuable in themselves, in the Gowganda area they may have a positive significance with regard to the existence of mineral deposits. They seem to occur most abundantly where differentiation of the diabase magma has proceeded farthest, and where, if the supposed relation between the diabase and the silver-cobalt mineralization does exist, conditions for the formation of mineralized veins would be most favorable.

The intimate connection between silver deposits and diabase at Gowganda lake naturally draws attention to other diabase bodies in the neighborhood. Of these the most extensive is a great sill-like mass which, beginning on Duncan lake at about three miles from its north end, is followed by that body of water fairly closely to its junction with the West branch; thence southward to where the West branch turns sharply east; thence east, crossing Wapus creek one mile from its mouth, and from there northeastward for about five miles, beyond which it could not be traced. In width it varies from 10 to 60, or more, chains. Very little work had been done on this body during the summer of 1908, although results of search had not been distinctly negative. Very thorough and well directed work was being done on Wapus creek, under the supervision of Robert Lett, with the result that numerous veins and aplite dikes had been exposed and, in cases, had yielded small quantities of bismuth and disseminated smaltite, also abundant bloom and chalcopyrite, but no free silver. The evidences of extensive differentiation at this point are promising signs. Bloom, chalcopyrite, and galena are also to be found throughout the diabase body as seen along Duncan lake.

*Abstracted from Summary Report, Geological Survey Branch, Department of Mines (Canada), 1908.

RUTILE DEPOSITS OF VIRGINIA.

Written for the MINING AND SCIENTIFIC PRESS
By a Special Correspondent.

The General Electric Co. is developing rutile deposits seven miles north and a little west of Tye River station, Nelson county, Virginia. Day and night shifts are now working. The rutile is used in making titanium carbide for electrodes in arc lamps. Ilmeno-rutile, a mineral which has a composition between that of ilmenite and rutile, is also used for similar purposes. It contains more titanium than ilmenite, and much more iron than nigrine, the iron-bearing rutile. It is easily differentiated from ilmenite by its purplish luster, though, like ilmenite, it gives a black powder when crushed. Rutile as found here has a glassy metallic luster, a peculiar purplish color, and gives a brown or light colored powder on crushing.

Both rutile and ilmeno-rutile occur on the property of the General Electric Co. in dikes, composed in the one case of rutile and apatite, and in the other of ilmeno-rutile and apatite. A small amount of ilmenite occurs in both kinds of dikes, and at times they contain some feldspar, and a small amount of biotite. The dikes range up to 5 ft. in thickness.

Ilmenite occurs with apatite in similar dikes, and all of these cut larger dikes of pegmatite which carries rutile. The ilmenite-apatite rock has been called 'nelsonite' by Thomas Leonard Watson, State Geologist of Virginia. The General Electric Co. some time ago shipped several carloads of rutile ore to a Pennsylvania firm for concentration. They have also shipped some of the ilmeno-rutile, and have further stocks of both ready for shipment.

The American Rutile Co. has not been working its deposit for some time, as it had a considerable stock of rutile on hand. This stock is now much depleted, and as the market is at present, active work on these deposits will resume at an early date. This property is at Roseland, about seven miles west of Arrington, Nelson county, and about 3½ miles from the General Electric Co.'s property. The deposit worked at this place is of a totally different character from that being exploited by the General Electric Co. The rutile occurs as an original constituent of a broad pegmatite dike of the same variety as that which forms the country rock on the General Electric Co.'s property at Roseland, and is sufficiently segregated to be workable. The other minerals contained in the dike are albite (forming much the greater part of the rock), bright blue quartz, hornblende, and minor amount of apatite. A small percentage of the concentrate is ilmenite and ilmeno-rutile. Where a very pure rutile product is desired, the latter minerals are taken out by a Wetherill magnetic separator. By this separation the TiO_2 , or pure rutile, is run up to over 99%. The firm has an excellent dike of rutile-apatite, so far not worked, as it is desired to keep the product free from phosphorus. There is also an ilmeno-rutile-apatite dike 30 ft. wide on this property. The American Rutile Co.'s workings are all open-cut. They are mining in the face of the hill on the north side of Tye river, from which the rock is quarried. Much of

it is decomposed and can be excavated and crushed easily. The dirt overlying the deposit contains a considerable percentage of residual rutile from the decomposition of the pegmatite, and is worked with the rock. Plans are being considered for more extensive working of this dirt. The company has a mill with 10 stamps, 3 Wilfley tables, and ample power and pumps for doubling the capacity of the crushing and separating plant.

Most of this company's product is used in making ferro-titanium for steel manufacture. Smaller amounts go into the making of dyes for leather, mordants, ceramic coloring, and arc-lamp electrodes.

Besides the deposits controlled by these two companies, ilmeno-apatite dikes occur at a number of places in the same region, and they are also found near Roanoke. No other rutile-apatite dikes are known, though there is much of the rutile-bearing pegmatite, but in most if not all of it the rutile is not sufficiently segregated to be profitably worked. Rutile-apatite dikes are not known to occur in any other place, though ilmenite-apatite dikes occur in New Jersey and Lapland. Rutile-bearing granite or pegmatite occurs in southern Norway, South Australia, and possibly in Queensland, Australia.

Some years ago a large iron company obtained control of several thousand acres of land in Nelson county, expecting to work the ilmenite-apatite dikes for iron. At other times there have been projects afoot for working the apatite-bearing dikes for phosphate of lime, but it was not found profitable in competition with the phosphates of the Carolinas and Florida.

DREDGING IN KELANTAN.

The Duff Development Co. owns the only four dredges on the Kelantan river, which flows to the east coast of the Malay Peninsula, and which is 600 to 800 ft. wide about 100 miles inland, at the place where the dredges have been working. During two months one of the dredges won 1600 oz. gold. The biggest return the company has had from one dredge was 375 oz. for one week. Each dredge has a master, 3 European winchmen—one for each shift—and about 16 native hands. The dredgemasters received a salary of about £400, the European winchmen about £200, and the native coolies, 50c. per day. Firemen and greasers got 60c., and native winchmen 70c. Expenses are considerably heavier than in New Zealand, but a man could have everything necessary for about £2 per week. Generally speaking, the climate is good. It is moist and warm, but not so oppressive as is generally supposed. The rainy season usually lasts only a week or a fortnight, and at such times the rivers rise perhaps 30 or 40 ft. in 24 hours, but fall again just as quickly. There are numbers of other smaller rivers on the Malay Peninsula, on which nothing has ever been done beyond a little prospecting.

Practically nothing has been done to develop the mining industry. There are fairly good prospects for mining, and when the country has been cleared a bit, good alluvial flats and some excellent quartz will probably be found.

Electro-Chemical Amalgamation.

Written for the MINING AND SCIENTIFIC PRESS
By D. F. MCGRAW.

The Alling method, which has been incorporated under the name of the Electro-Chemical Gold Saving System, consists of a sluice-box which is made in various sizes and forms to successfully carry out the work it is designed to do, taking the pulp from the battery, also sand and gravel from the sluice-boxes after it has been screened to No. 8 or finer mesh. A standard-size machine which will care for 50 tons of pulp from a mill, or the same number of tons of sand and gravel concentrate per day of 20 hours, is 12 ft. long, 72 in. wide, inside measurement. It consists of 32 riffles, 24 of which are mercury cups, 2 ft. long, 7/8 in. deep, and 1 in. wide at the top. The first two riffles at the top of the machine spread the material, the last eight catch any 'flour quick' that may come through with the pulp from the battery, or be in the sand or gravel in hydrauliclicking or ground-sluicing. There are six sets of four mercury cups, into which are placed carbon electrodes, 2 ft. long, 2 1/2 in. wide, and 5/8 in. thick. These carbons serve the double purpose of anode and baffleplate. After each series of mercury cups is a copper plate, silver plated, 2 ft. long by 7 in. wide, having as anodes copper brushes, coming into contact with the water, to insure sufficient amperage.

Electro-Chemical Amalgamator.

These brushes are regulated so that any amperage from 1/10 to 3 per square foot can be obtained, as the different classes of material demonstrate to be necessary. It is rare that 3 amperes will be necessary. These brushes do not interfere with the flow of the material through the machine. The last eight riffles have iron baffle-plates. Both carbon and iron plates are fixed firmly in the machine, but are easily removable for the purposes of cleaning up.

Material entering the machine is evenly distributed by the first two riffles. It then comes in contact with the first set of baffle-plates, which depress the entire mass into the mercury cups, and it then runs over the silver plate, striking another series of carbon and mercury cups. It continues until it has passed the baffle-plates and has been depressed into the 24 cups. By this time the gold and platinum has been deposited on the plates and in the cups, but there may be 'flour quick' which carries gold. To save this, the 8 riffles with the iron baffle-plates, below the mercury cups, have been provided.

Mercuric chloride in solution is the chemical used in connection with the electric current. It is fed into the machine with the material. It is very diffusible in water, mixing in a similar manner to that of milk and tea. The electric current being turned decomposes the mercuric chloride into its original component parts of mercury (nascent quicksilver) and chlorine. The mercury being metallic, and electro-positive, seeks the cathode, which is the copper plates and mercury cups, being the bottom portion of the machine. The chlorine being non-metallic, and electro-negative, seeks the anode, which is the carbon baffle-plates. The chlorine, as it has parted from the mercury, is constantly coming in contact with the fine particles of gold that are floating in or on the top of the water or pulp, and cleans them from all grease or rust, leaving the gold in a perfect state for amalgamation. The material is constantly being turned over by coming in contact with the baffle-plates and the consequent depression

into the mercury-cups, which places all of the particles of gold where they are constantly surrounded by newly formed quicksilver, or, as one very happily put it, the "gold is in a mercury fog until it's caught." When the gold particles have been covered with this fresh quicksilver they attach themselves to the plates, or are caught in the mercury cups as they pass through, their weight, with the mercury with which they have been amalgamated, being more than sufficient to give the gold the required specific gravity to reach the bottom of the machine.

By this electric action fresh quicksilver is constantly being deposited on the plates, keeping them 'dressed' or in a condition for the most perfect form for amalgamation. The same electrical action keeps the mercury constantly 'alive and bright' in the mercury cups.

Under normal conditions mercury has no amalgamating power with platinum. Several instances have occurred, however, in our tests where a current of 30 volts has amalgamated platinum and gold perfectly. In other cases with the same voltage, and seemingly the same conditions, no amalgamating tendency was shown. The appliance has been saving from 97 to 99% of the assay values of all platinum-bearing material that has been submitted. The following tests were made on difficult gold and platinum-bearing material. The material was weighed, assays made of the 'heads' and again of the tailing after passing through the machine; black sand concentrate sized to number 10 mesh, from the Hess & Hagerman mine, Jolon, Monterey county, California; reported on by Ernest H. Simonds, of San Francisco:

Samples, 2.	Heads,	Tailing.
	gold.	gold.
1.....	\$31.00	\$0.40
2.....	44.00	0.41

Disintegrated quartz and porphyry; ground to No. 100 mesh; Dayton, Nevada; reported on by Smith, Emery & Co., San Francisco:

Samples, 4.	Heads,	Tailing.
	gold.	gold
1.....	\$11.58	\$0.20
2.....	7.34	0.40
3.....	5.17	0.41
4.....	4.96	0.41

Black-sand concentrate sized to number 10 mesh; 80% of mass magnetic iron, carrying a large amount of 'flour' quicksilver; reported on by Harold G. Ward, of the C. A. Luckhard Assaying Co., San Francisco:

Sample, 1.	Heads		Tailing	
	Gold.	Platinum.	Gold.	Platinum.
1.....	\$156.07	\$74.40	\$0.41	\$0.81

The machine was cleaned thoroughly, and re-distilled mercury was used in the cups. After the material had been run through the machine it was cleaned up, the mercury retorted, and the clean-up compared with the assay-values. Comparable results have been obtained in fully 200 tests. The significance of such figures will appeal to all who are familiar with the metallurgy of gold and silver.

Production of Coal in Oregon in 1908.

The total production of coal in Oregon in 1908, as shown by statistics collected by E. W. Parker, of the United States Geological Survey, was 86,259 short tons, having a spot value of \$236,021. Oregon, like California, is one of the few States in which the coal production in 1908 showed an increase over that of the preceding year, which was 70,981 short tons, the 1908 output being therefore a gain of 15,278 short tons, or 21.52%; the value increased from \$166,304 to \$236,021, a gain of \$69,717, or 41.92%. All of the coal produced came from the Coos Bay field, in Coos county, and the increased production in 1908 was due to an increased activity at the Beaver Hill mines. All the Beaver Hill coal was washed, the operations yielding 70% cleaned coal. The coal from this field is of lignitic character. The average number of men employed increased from 184 in 1907 to 214 in 1908, and the average number of days worked increased from 231 to 249. There were no labor disturbances during the year.

Mineral Production of New York in 1908.*

Product.	Unit of measurement.	Quantity.	Value.
Portland cement	Barrels	1,988,874	\$1,813,623
Natural rock cement...	Barrels	623,618	441,136

Total value	\$29,517,942

*Statistics collected by John M. Clarke, State Geologist, in co-operation with the U. S. Geological Survey.

†Includes apatite, carbon dioxide, diatomaceous earth, and marl.

Commercial Paragraphs.

The STANDARD UNDERGROUND CABLE Co. has moved its San Francisco office to the First National Bank building.

The KEYSTONE PLACER DRILL Co., Beaver Falls, Pa., has made shipment of seven large double-stroke geared deep-well pumps for the town of Zacatecas, Mexico. The pumps are part of a million dollar water-supply plant for the city which is being installed by the Government of Mexico.

CROCKER & KETCHUM is the style of a newly formed partnership for practice as consulting engineers along the lines of steel and reinforced construction, mine and mill buildings, examinations and reports. The partners are Herbert S. Crocker and Milo S. Ketchum. Their offices are at 811 Seventeenth street, Denver, Colorado.

The AMERICAN LOCOMOTIVE Co. has recently issued pamphlet No. 10035, describing the joint exhibit of that company and the Atlantic Equipment Co. at the Alaska-Yukon-Pacific Exposition, in progress at Seattle, Washington. The exhibit consists of a rotary snow-plow; two locomotives, one a six-coupled tank or 2-6-2 T type locomotive for logging service, and the other a 10 by 16-in. four-wheel saddle-tank contractor's locomotive; an electric motor and trailer truck, and a new model Atlantic steam-shovel.

The WOOD DRILL WORKS, Paterson, N. J., has appointed Fairbanks, Morse & Co., of Seattle and Spokane, Washington, as exclusive representatives for the State of Washington. A large stock of drills, accessories, and repairs are now on hand at the Spokane and Seattle stores, with catalogues and full literature on the Wood rock drill, including the company's latest booklet, 'Glimpses of the Panama Canal'. On exhibit at Seattle is a nickel-plated 2½-in. drill, so perfect in workmanship and construction that the drill can be operated by the human breath.

Utah's Coal Output in 1908.

The total production of coal in Utah in 1908, according to information obtained by E. W. Parker, of the U. S. Geological Survey, was 1,846,792 short tons, having a spot value of \$3,119,338. The figures show a decrease of 100,815 short tons, or 5.18%, in quantity, but an advance of \$159,569, or 5.39%, in value in price over 1907. The average price per ton rose from \$1.52 to \$1.69. This increase in value and advance in price, in the face of the general financial depression, can be accounted for only by the increased expense of mining due to a lessened productive capacity of the mine-workers. In 1905 the average daily production for each man employed in the coal mines of Utah was 396 tons; in 1906 it was 392 tons, in 1907 it was 343 tons; and in 1908 it was 305 tons. Practically all the mines in the State are operated under agreements with the United Mine Workers of America, and out of a total of 2664 men, 2620 worked at mines operated on the basis of an eight-hour day. As in the other coal-producing states of the Rocky Mountain region, the number of men employed in the mines shows an increase from 2208 in 1907 to 2664 in 1908. The average number of working days decreased from 258 in 1907 to 227 in 1908. The supply of cars was in general ample throughout the year, and there was no trouble from strikes, lockouts, or other labor difficulties. The second half of the year showed a marked improvement over the first half, and the conditions in the metalliferous mining industry at the end of the year were gradually improving, so that the outlook for the coal mines in 1909 was hopeful.

Antimonial Lead.

During the years 1907 and 1908 antimonial lead was produced in the United States, according to the U. S. Geological Survey, as follows:

	1907.	1908.
Antimonial lead	9,910	13,629
Antimony contents	1,560.5	2,440
Approximate percentage of foreign origin...	27	37

A considerable quantity of antimony was recovered from drosses, old type metal, and similar sources by firms making a specialty of this branch metallurgy, but complete figures are not at hand. There was no production of metallic antimony from domestic ore in 1908.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

OIL AND GAS IN THE ST. LUIS DISTRICT. By H. A. Wheeler. Jour. Assoc. Eng. Soc., Vol. 1 No. 4, pp. 188-199. April 1909.

SOME CENTRAL IDAHO GO DISTRICTS. By S. P. Jellum. 8vo., pp. 83. Northwest Min. News. Spokane, 1909. Price 50 cents.

PRODUCTION OF CEMENT CANADA, 1908. By John McLeish. Department of Min. Mines Branch. 8vo., pp. 4. Ottawa, 1909.

PRODUCTION OF SALT AND OMINE IN 1908. By W. C. Phalen. Advance chapter Mineral Resources of the United States, U. S. Geol. Surv., p. 18. Washington, 1909.

GEOLOGY AND WATER RESOURCES OF THE HARNEY BASIN REGION, OREGON. By Gerald A. Aving, U. S. Geol. Surv., Water Supply Paper 231. 8vo., p. 13, map. Washington, 1909.

Catalogs Received.

The DEARBORN DRUG & CHEMICAL WORKS, Chicago, is distributing an attractive booklet called 'Lubrication Versus Friction.' Send for it.

The WESTINGHOUSE ELECT. & MFG. Co., in its folder No. 4132, shows many novel and practical uses for electric motors around the shop, stored office.
